SECTION 11 CONSERVATION AND WILDLIFE MANAGEMENT

CHAPTER 48

Introduction to Anthropogenic and Environmental Threats to Avian Wildlife

Heather W. Barron

Visit eBooks.Health.Elsevier.com for a complete set of references.

The industrial age has brought an increasing number of anthropogenic threats to earth's environment and the wild flora and fauna that inhabit it, birds being notable among these. In North America alone, it is estimated that 3 billion birds have been lost over the past 50 years.[1] Despite these losses, the laws that have shielded migratory birds for over a hundred years have been under political assault and have been weakened at a time when further legislation is needed to protect this valuable segment of earth's biodiversity. Many variables factor into this significant loss but include a variety of anthropogenic factors and a declining environment. As the human population exceeds 7 billion people, natural habitats are increasingly lost or rendered unsafe for avifauna. This section addresses some of the more notable and currently pressing threats to avian wildlife health, including man-made obstacles (e.g., wind turbines and windows), domestic cats, and climate change–induced threats, such as wildfires and extreme weather events. These, alongside nutrient pollution, also contribute to more environmental biotoxins (e.g., harmful algal blooms). Finally, globally roughly 400 million tons of chemicals are produced annually, a number of which are persistent and bioaccumulate.[2] Included here for consideration are petroleum products, heavy metals (e.g., lead), Superfund sites, and pesticides. It has been decades since the discovery that some organochlorine pesticides (e.g., dichlorodiphenyltrichloroethane [DDT]) caused eggshell thinning in wild birds, which led to bans on its use in some countries, such as the United States. However, DDT continues to be used in many countries and the effects of this chemical and its active breakdown products (dichlorodiphenyldichloroethane [DDD], dichlorodiphenyldichloroethylene [DDE]) linger in the environment for decades and are still causing decreased hatchability, for example, in bald eagles *(Haliaeetus leucocephalus)* in the US Great Lakes region.[3] Equally concerning is the fact that these chemicals are still currently found in 99% of humans tested.[2] With growing understanding of these toxins comes the awareness that damage may occur not just from the high-dose acute effects but also from low-dose chronic exposure, which may render these compounds into carcinogens, mutagens, endocrine-disrupting chemicals (EDCs), or have other impacts, such as behavioral modification. These effects, while perhaps less dramatic and obvious initially on the surface, are insidious, alarming, and just as damaging to wild bird population health in the end.[4,5]

The increasing convergence of animals and a growing number of people on an increasingly stressed earth has created a new dynamic in which the health of each of these entities is interconnected. The study of this combined health has become known as conservation medicine and calls for the collaborative efforts of multiple disciplines working to attain optimal "One Health" for all. Diseases that move from wildlife to people are a daily discussion for wildlife veterinarians. According to the Centers for Disease Control and Prevention (CDC), more than 6 out of every 10 infectious diseases in humans are zoonotic. However, only when there is an outbreak of avian influenza, West Nile Virus, or SARS-COV-2 does the importance of wildlife health seem to resonate with the general public. Thus there is a growing need and demand for veterinary expertise to address wildlife, and often in particular, avian health.

CHAPTER 49

Biotoxins

Heather W. Barron

Visit eBooks.Health.Elsevier.com for a complete set of references.

HARMFUL ALGAL BLOOMS

Algal toxins encompass a wide variety of naturally occurring toxins produced by different species of diatoms, algae, and cyanobacteria. During periods of growth or blooms, which are large concentrations of aquatic microorganisms such as protozoans and unicellular algae (e.g., dinoflagellates and diatoms), toxins may be produced that can be hazardous to animals and people. Only about 2% of blooms are known to be toxic. These blooms, often referred to as harmful algal blooms or HABs, occur worldwide. Occasionally they may discolor the water, and thus "red tides" are a common name for several types of algal blooms (Figure 49.1). In one documented occurrence, a red tide caused by a bloom of nontoxic dinoflagellate *Akashiwo sanguinea* caused debilitation and death in a variety of seabirds by producing a surfactant that impaired waterproofing of plumage (Figure 49.2).[1]

For most HABs, biomagnification occurs as the toxic organisms accumulate in the animals that ingest them, following which the toxin becomes more concentrated as it passes up through the food chain. Although these HABs have been documented for hundreds of years, growing evidence indicates that the frequency and intensity are increasing.[2] As an example, seabird "wrecks" and mass mortality events of other marine animals are being more frequently associated with HABs. HABs are a serious threat to human, wildlife, and ecosystem health and veterinary practitioners can be an important component in efforts to combat this growing problem. Common algal toxins affecting birds may include domoic acid, cyanotoxins (including saxitoxin and microcystin), and brevetoxins. Birds exhibit a wide range of sensitivities to algal toxins and symptoms vary depending upon the species of bird, the algal toxin, the dose, and the route of exposure (ingestion, dermal, or inhalation).

The occurrence of cases is not always correlative with documented HAB alerts in the area. Algal blooms may occur in another area that is not being monitored, birds may pick the toxins up along their migratory route, or blooms may occur offshore where there is no monitoring. Additionally, a bloom may have occurred several weeks earlier, and shellfish may harbor these toxins for weeks to months before the birds ingest them and are finally exposed.[3] There is also some evidence that birds learn not to eat toxic fish and shellfish over time through conditioned aversion. In the author's experience, over 90% of brevetoxin-affected seabirds are first-year birds. Several authors[4–6] have provided detailed accounts of the impacts of domoic acid (DA) on seabirds in California and Mexico, respectively. In both places, the birds killed (predominantly cormorants [*Phalacrocorax* spp.] and pelicans [*Pelecanus* spp.]) were piscivorous and naive. However, this author has also seen the same individual birds present repeatedly with brevetoxicosis over the course of a single red tide season. It is possible that, as first-year seabirds are less proficient at hunting, these younger individuals may eat affected fish out of desperation, whereas seasoned adults can afford to be more selective. Alternatively, birds may also be exposed through inhalation, although the age distribution of juveniles being affected almost exclusively argues against this. In Maine waters, it has been reported that adult eider ducks *(Somateria mollissima)* avoid toxic mussels under field conditions during annual blooms of *Alexandrium* catenella (formerly A. *tamarense*), which produce saxitoxins. In laboratory studies, eider ducks were offered toxic versus nontoxic mussel meats and they refused the toxic mussels. Those that were force-fed toxic mussel meat regurgitated the food almost immediately.[7]

It is not only wild birds that may be affected. Naar et al.[8] reported four king penguins *(Aptenodytes forsteri)* from a zoo in Kentucky died after being fed fish caught in Monterey Bay, CA, that were found to have high levels of DA. Therefore, animals in captive settings may also be at risk. However, the full impact of HABs on birds is likely underestimated since most free-ranging birds that die at sea are lost to follow-up. Shags *(Phalacrocorax aristotelis)* and other species of cormorants are documented in HAB mortality events more often than other birds, which undoubtedly is a function of their feeding habits (consumption of whole prey with no sampling or testing), choice of food items, and their coastal habitat (more likely in affected HAB zones and more visible once affected). HAB toxins should always be on the differential list for birds with clinical signs (as elucidated here) that may have consumed prey items from areas with a history of HABs. Diagnosis may be difficult. In some cases, a suspected diagnosis is made based on clinical signs exhibited by the birds and reported environmental conditions (including HAB alerts and public health advisories), which may or may not include the presence of algal mats, discoloration, and/or the detection of the algal species in the water where mortality has occurred.

Domoic Acid

DA is a structural analogue of glutamic acid produced by several related marine diatoms (microalgae) in the genus

FIGURE 49.1 Waters around Sanibel Island, FL, showing high counts of *Myrionecta rubra* algae and demonstrating that not all "red tides" are due to *Karenia brevis*. (Photo courtesy Rick Bartelson, Sanibel-Captiva Conservation Foundation.)

Pseudo-nitzschia, including *P. australis* and *P. pungens*. Blooms of this algae can cause "red tides," which may occur in marine waters throughout the world and may be caused by several different types of diatoms, not all of which are harmful.

The form of biologically available nitrogen has a significant effect on the ability of *Pseudo-nitzschia* to multiply and produce DA. Urea is much more potent at stimulating DA and DA-related toxicity than nitrates or nitrites.[9] As the end product of nitrogen metabolism, the sources of urea in marine environments may be natural (e.g., elasmobranchs and marine mammals) or anthropogenic (sewage, agricultural runoff, or fertilizers containing urea).

DA is a neurotoxin that in humans may cause a variety of neurologic signs, including short-term memory loss, leading to the initial designation of the clinical syndrome in people as amnesic shellfish poisoning (ASP). Since 1987, monitoring programs have been largely successful in preventing human incidents of ASP. However, wildlife continues to be at risk worldwide. In birds, DA primarily attacks the brain, causing lethargy, disorientation, fine motor tremors, opisthotonos, seizures, scratching (pelicans will scratch their pouch), vomiting, and death. Behavior may remain altered in affected birds for up to 2 weeks, according to one report.[10] Some evidence indicates that mitochondrial dysfunction and oxidative stress are involved in DA-induced cognitive functional impairment.[11]

DA has also been shown to cause other organ dysfunction in mammalian species and thus these pathologies may potentially also occur in birds. Cardiomyopathy has been documented in sea lions *(Zalophus californianus)* and otters *(Enhydra lutris)*.[12,13] Unstable blood pressure and cardiac arrhythmias may be observed in many species and can be suggestive of a cardiotoxin. Research in mice found that DA levels 100 times lower than

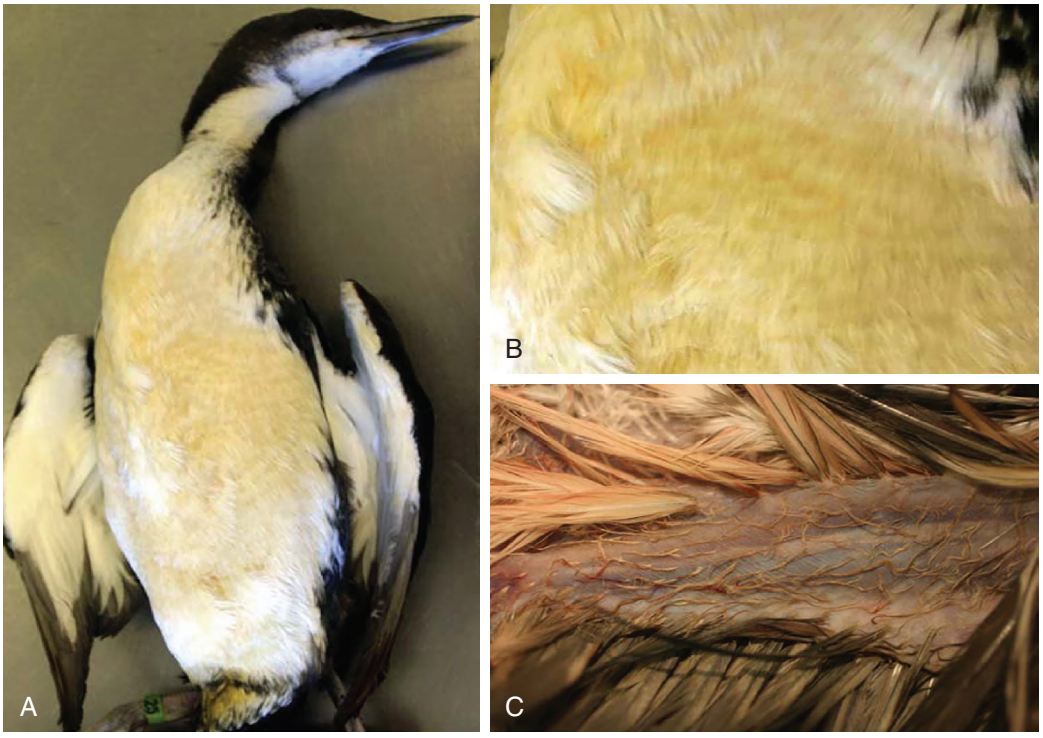

FIGURE 49.2 Dead seabirds with signs of protein-induced loss of waterproofing. (A) A Pacific loon *(Gavia pacifica)* found dead in Monterey Bay, CA, in November 2007 with yellow-green staining of ventral breast feathers typical of over 700 marine birds affected by this event. (B) Closer view of the stained feathers from (A), illustrating the yellow-green discoloration and the oily appearance of affected feathers. (C) Discolored, wet, and matted feathers on the ventral wing of a western grebe (*Aechmophorus occidentalis*) recovered during the same stranding event. (From Jessup DA, Miller MA, Ryan JP, et al: Mass stranding of marine birds caused by a surfactant-producing red tide. *PLoS One* 4(2):e4550, 2009.)

what is necessary to cause neurologic effects can cause renal damage.[14] Gastrointestinal (GI) ulcers may also be noted in affected animals. Seabirds affected by DA commonly include pelicans, murres, (*Uria* spp.), loons (*Gavia* spp.), grebes (Podicipedidae), cormorants, and shearwaters (Procellariidae). Current laboratory diagnostic methods for DA intoxication are challenging as the toxin is highly water soluble and excreted from affected animal's system within 2 to 48 hours, depending on the amount ingested and species of bird. However, DA can be measured in gastrointestinal contents, urine, or serum/plasma if samples are obtained early upon admission.

The mainstay of treatment is supportive care, including nutritional support, diazepam as needed to control seizures, and aggressive intravenous (90–120 mL/kg/day) and oral (tube, 3%–5% body weight, two to three times per day) fluid therapy. Crystalloid fluid choice is usually based on i-STAT results, but Normosol-R is a good empiric choice. As these patients are often hypoproteinemic, colloidal fluid support may also be indicated. Additionally, one study showed that the oral administration of a bioflavonoid called quercetin to DA-treated mice significantly improved their behavioral performance in a novel objective recognition and maze task.[11] Others have suggested nutraceuticals including alpha-lipoic acid (ALA), which is a precursor for glutathione. ALA has been utilized in sea lions with DA toxicosis to improve clinical neurologic signs and may be a consideration for birds.[15] Recovery may be prolonged, generally taking at least 2 weeks, and prognosis is often guarded with previous reports suggesting a 42% survival rate.[10,16]

Cyanotoxins

Cyanotoxins are toxins produced by bacteria called cyanobacteria. Also known as blue-green algae, cyanobacteria are found almost everywhere, in marine, brackish, and freshwater, and under the right conditions blooms may form mats of bright green algae with a putrid odor. There are more than 30 species of cyanobacteria that can be associated with these toxic blooms. Neurotoxic alkaloids (called anatoxins) can be produced by *Anabaena*, *Aphanizomenon*, and *Planktothrix*, while saxitoxins (also called paralytic shellfish toxins) can be produced by *Anabaena*, *Aphanizomenon*, and *Lyngbya* and form potent, presynaptic sodium channel blockers. Hepatotoxic heptapeptides called microcystins can be produced by *Anabaena*, *Microcystis*, *Nostoc*, and *Planktothrix*. Blooming cyanobacteria can produce cyanotoxins that may affect the nervous or respiratory system, liver, or skin. The toxins tend to act rapidly after ingestion, causing neurologic signs within minutes and liver hepatopathy within a few hours as the liver attempts to process these toxins. In one report, deaths of over 100 birds were associated with a microcystin toxicity and some of the affected birds (great blue herons; *Ardea herodias*) were documented to have steatitis.[16]

Typically, clinical signs in affected birds may include depression, dyspnea, vomiting, diarrhea, ataxia, opisthotonos, and seizures. Affected birds may present with blue-green algae in the plumage (Figure 49.3). Death occurs from ingestion of alkaloids leading to neurotoxicosis that produces respiratory arrest or may be induced by cyclic peptides causing acute hepatotoxicosis leading to intrahepatic hemorrhage and hypovolemic shock. Diagnosis can be presumptive based on clinical signs concurrent with area HABs and confirmed with

FIGURE 49.3 A Florida mottled duck *(Anas fulvigula)* receives treatment after presenting with neurologic signs associated with exposure to blue-green algae. In 2018, Florida declared a state of emergency due to the severity of toxic cyanobacterial blooms in Lee and other counties on the Gulf Coast.

enzyme-linked immunosorbent assay (ELISA) kits in both laboratory and field formats for microcystins/nodularin, cylindrospermopsin, and saxitoxins. Affected birds often have anemia and hypoproteinemia.[16]

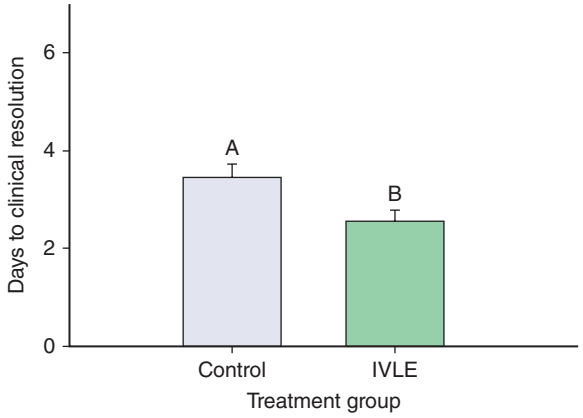
Treatment is predominately aimed at supportive care, such as oxygen support, fluid therapy, control of seizures with diazepam, and correction of anemia, electrolyte, and acid/base imbalances. Preventing further absorption of toxins from the gut with activated charcoal or administration of cholestyramine may provide some benefit, but death following toxin ingestion is often rapid, and birds are typically found deceased with no real opportunity to treat. Prognosis is guarded to grave.

Brevetoxins

Brevetoxins (PbTx) are algal toxins produced by dinoflagellate *Karenia* spp. (especially *K. brevis*) that may produce "red tides." The major brevetoxin produced is PbTx-2, followed by lesser amounts of PbTx-1 and PbTx-3. Fish, birds, and mammals are all susceptible to the brevetoxins. Animals and people may be exposed by ingestion or inhalation of the toxins, which are lipid-soluble polycyclic ethers that bind to and stimulate sodium (Na+) flux through voltage-gated channels in nerve and muscle. This causes neuronal and muscle cell depolarization, leading to neurologic, gastrointestinal, respiratory, and other signs in affected individuals. In humans, ingestion leads to neurotoxic shellfish poisoning (NSP), but humans are more commonly exposed via inhalation of the toxin.

Morbidity and mortality in birds from HABs is an annual event in many places and is of concern in conservation medicine as avian populations continue to dwindle, and the length and severity of these "red tides" increase. Birds with brevetoxicosis may exhibit ataxia, tremors, depression, gastrointestinal upset (e.g., ileus, diarrhea, melena, hematochezia), bradycardia, lagophthalmos, and respiratory distress. In one report, hundreds of common murres *(Uria aalge)* dying off the coast of California from brevetoxicosis exhibited serosanguinous rhinitis and pulmonary edema as the predominant clinical signs.[17] Differential diagnoses, such as Newcastle disease (paramyxovirus; PMV-1) and botulism, are important to rule

out. Hematologic and biochemical abnormalities are common in affected animals.[18–20] Plasma protein levels may serve as a prognostic indicator in cormorants (and possibly other species) with brevetoxicosis. In one study, the probability of survival was only 50% at total protein levels of 2.3 g/dL, whereas at protein levels of ≤1 g/dL, the probability of survival was 20% or less.[20] Total protein is likely decreased due to effects of the toxin causing damage to the GI tract and subsequent protein-losing enteropathy, chronic GI blood loss, and hepatopathy. Concomitant anemia is often present and degrades the prognosis further. Affected birds are often heavily parasitized with both ecto- and endoparasites, commonly including GI nematodes, and, in some cases, tracheal worms, which may exacerbate respiratory symptoms.[21]



Species commonly affected with brevetoxicosis include double-crested cormorants *(Phalacrocorax auritus)*, brown pelicans *(Pelecanus occidentalis)*, great blue herons, common loons *(Gavia immer)*, and a variety of gulls (*Larus* spp.), terns (*Sterna* spp.), and other Charadriiformes. Interestingly, the species of bird may affect clinical presentation, with cormorants typically showing predominately ataxia, disorientation, and head tremors, while pelicans most commonly show weakness, depression, and GI distress (regurgitation and diarrhea). Gulls and shorebirds, such as sanderlings *(Calidris alba)*, often present with rear limb weakness or paresis. Any species may demonstrate a delayed or absent palpebral reflex, loss of vent tone, and seizures. In the author's hospital, double-crested cormorants are the predominant species presenting with brevetoxicosis during the "red tide" season, which typically runs from October to April on the Gulf Coast of Florida. Cormorants are piscivorous and opportunistic and may prey upon sick or dying fish. In one study, brevetoxin levels in freshly dead fish tissues ranged from 32 to 95,753 ng PbTx g-1. Brevetoxins in shorebird livers were also confirmed (26–1313 ng PbTx g-1) in dead birds collected opportunistically from local beaches and rehabilitation centers during the red tide event, suggesting that brevetoxin exposure is a risk factor for mortality.[22]

Brevetoxin can be assayed by using a mouse bioassay, ELISA, and antibody radioimmunoassay. In clinical veterinary medicine, diagnosis is usually through a competitive ELISA that may be run on plasma or serum (be consistent in which one is used), GI contents, or liver. Sea birds are predominately exposed to PbTx-3, a reduced form of PbTx-2 that is up to 10 times more toxic than PbTx-2 when ingested.[23] Results are expressed in nanograms per gram or milliliter as PbTx-3 equivalents and reflect the overall concentration of brevetoxins and brevetoxin-like compounds in the sample. The detection limit of the assay is approximately 5.0 ng PbTx-3 eq/g of tissue and 2.0 ng PbTx-3 eq/mL of fluid. However, higher levels are common in affected animals and values may be extrapolated through serial dilutions. Levels can be very high in fecal samples, which are easily collected and, in one study, ranged up to over 900 ng PbTx-3 eq/g) in affected cormorants.[24] Interestingly, toxin levels are not correlative with clinical presentation or survival. Toxins are processed by the liver and excreted by the kidneys and in bile.[25] Most dead birds had no significant pathologic findings at necropsy.

Treatment often includes parenteral fluids, nutritional support, antimicrobials, antiulcer medications, antiparasitic medications, blood or plasma transfusions, B vitamin and iron supplementation, ocular medications (in patients unable to blink or with corneal ulcers), manual evacuation of cloacal contents (as required), intravenous lipid emulsion therapy (ILE) (Figure 49.4), and thermal support, if indicated. Birds with active seizures can be treated with midazolam at 0.5 to 1.0 mg/kg intramuscularly or intravenously, whereas birds that were highly stressed in the hospital environment have been given diazepam at 0.5 to 2.0 mg/kg PO every 12 hours for as long as hospitalization lasted. Clearance of the toxin in birds typically takes 1 to 7 days.[26] Clearance is not necessarily more rapid after treatment with ILE, but birds' clinical signs are ameliorated much more rapidly and prognosis for survival is much greater (Figure 49.5). This is possibly because brevetoxin is a lipid-soluble toxin and the ILE solution serves as a "lipid sink" that holds the toxin bound in circulation and prevents it from reaching target tissues until it is excreted.[27]

FIGURE 49.4 Double-crested cormorants *(Phalacrocorax auritus)* receiving intravenous lipid emulsion (ILE) therapy as a treatment for brevetoxicosis. Resolution of neurologic signs was achieved within 24 hours in this case.

Kruskal Wallace test with w/ Cover-Innman Pairwise comparison was used due to the non-normal distribution of data. Test shows comparison of control and IVLE with Days it took till clinical resolution. $P = 0.030$, suggesting significance between control and IVLE. Birds in the IVLE treatment group had clinical resolution, on average, 24 hours earlier than control birds.

FIGURE 49.5 Use of intravenous lipid emulsion therapy for brevetoxicosis in double-crested cormorants *(Phalacrocorax auritus)* significantly improved time to resolution of clinical signs. (Barron H, unpublished data, 2017.)

BOTULISM

Botulism is a disease resulting from ingestion of preformed exotoxins produced by *Clostridium botulinum* and produces an ascending flaccid paralysis that is often fatal. The botulinum toxin is initially inactive when released, and bacterial or tissue proteases are needed to activate the toxin. Spores only contain about 1% of the toxin amount that vegetative cells do. Interestingly, some species of wildlife that have evolved to eat carrion are resistant to botulinum toxin. Virginia opossums *(Didelphis virginiana)* and vultures are good examples. Turkey vultures *(Cathartes aura)* are 100,000 times more resistant to type C botulinum toxin when compared to pigeons *(Columba livia)*.[28] Opossums have a proteinase inhibitor, called lethal toxin–neutralizing factor (LTNF), that occurs naturally in their blood and binds to toxins thus conferring botulinum resistance.[29]

There are four genotypically distinct groups (I–IV) and seven immunologically different types of botulinum toxins (A–G). Waterfowl die-offs are usually from type C (group III); sporadic die-offs among fish-eating birds (common loons, gulls) are from type E toxin, and domestic chickens (*Gallus gallus domesticus*) can be affected by type A (group I). *Clostridium botulinum* spores persist in the soil for years. Toxin production occurs during multiplication of the vegetative form when conditions (warm temperatures in alkaline and anaerobic environments with a source of protein) are favorable. The toxin production often takes place in decaying animal carcasses. Maggots of flies feeding on carcasses concentrate the toxin, and birds eat the highly toxic maggots. Death of the bird then perpetuates the cycle. Removal of carcasses was not shown to be helpful to remaining ducks on the lake in one study.[30] However, under some circumstances, carcass pickup, use of hazing devices to deter bird concentration in an outbreak area, and draining or flooding of fields have been used successfully for management of waterfowl botulism outbreaks.[31]

More than a million deaths have been reported in localized outbreaks, and deaths of 50,000 or more birds are common. Most outbreaks in the United States occur west of the Mississippi River in July through September but certainly there may be individuals that may be affected at any time of the year that flies are viable. The toxin affects peripheral nerves and results in an ascending flaccid paralysis of voluntary muscles, including the muscles of the neck, which explains the colloquial moniker, "limber neck" (Figure 49.6). Paralysis of the nictitating membrane may also occur. Large outbreaks of type C avian botulism at the Salton Sea documented thousands of sick and dying pelicans and other piscivorous birds. Death is often from drowning or from respiratory failure. Important differentials include infectious diseases like avian influenza, Marek disease, duck viral enteritis, and other toxins, such as algal toxins, organophosphates, lead, and castor bean toxicosis. In botulism cases, flight and leg muscles are affected first, so birds become unable to walk and fly. This helps differentiate paralysis due to lead poisoning, which is more spastic than flaccid, and in which birds lose flight ability but are still able to walk. Time to onset of clinical signs after ingestion of the toxin is dose dependent and may be hours to days.

Presumptive diagnosis of botulism is generally made from clinical signs and can be confirmed by detection of the toxin in the serum or GI contents of affected birds. In carcasses it may be more difficult to diagnose because there are no distinct gross or microscopic lesions, but maggots found in the GI tract may be suggestive. GI contents from moribund or very freshly dead birds may also be collected for toxin detection via ELISA or polymerase chain reaction (PCR) (mouse bioassay is the gold standard test but is discouraged for ethical reasons).[32,33] Samples from birds that have been dead for several hours are unreliable because *C. botulinum* toxin can result from postmortem multiplication of the organism and toxin production. Because botulinum toxins are heat labile, samples must be refrigerated or frozen as soon as possible after collection and shipped with ice packs to the testing laboratory.

FIGURE 49.6 Brown pelican (*Pelecanus occidentalis*) with probable type C botulism displaying the classic "limber neck" posture due to ascending paralysis.

Treatment with commercial botulinum antitoxin was shown to be 96.5% effective in one case study in wild birds affected in a natural setting but may be cost prohibitive.[34] Two preparations of botulinum antitoxins are available for treatment of botulism. Trivalent (A, B, E) botulinum antitoxin is derived from equine sources using whole antibodies. The second antitoxin is heptavalent (A, B, C, D, E, F, G) botulinum antitoxin, which is derived from equine antibodies that have been altered to make them less immunogenic. This antitoxin is effective against all known strains of botulism, except for strain H. Otherwise, give supportive care as described for brevetoxicosis. Recovery may take days to weeks as the receptors on the nerves regenerate, but prognosis is generally excellent if the patient survives the first couple of days. Mortality rate can vary from less than 10% up to 40% or more. In some large epornitics, a million or more wild birds may die.

Prevention involves removing decaying vegetation or carcasses to prevent maggot accumulation. In hot, alkaline farmlands in the western United States, delaying irrigation until after winter temperatures arrive can be helpful. There is no approved vaccine labeled for use in wild birds. Active immunization with inactivated type C bacterin-toxoids has been successful in pheasant operations. Additionally, two separate studies reported a vaccine labeled for use in mink was used successfully in ducks to reduce morbidity and mortality from type C botulism but was found to be less efficacious as botulinum dose increased.[35Î37]

CHAPTER 50

Hazards Related to Man-Made Structures: Buildings, Noise, Electric Power

Glenn H. Olsen

Visit eBooks.Health.Elsevier.com for a complete set of references.

INTRODUCTION

Many human-made structures can be hazardous to avian wildlife. The most common hazard is one of collision, and this chapter will review problems with glass in buildings, power lines, and wind turbines as sources of collision and trauma to avian wildlife. However, avian wildlife can also be adversely affected by anthropogenic factors that effectively eliminate suitable habitats for avian wildlife. These can include noise factors associated with such things as wind turbines and construction areas, and habitat loss to large solar arrays, not to mention strip mining for coal and oil sands. All these factors have likely contributed to the estimated loss of 3 billion birds in the last five decades.[1]

BUILDING (GLASS) COLLISIONS

Building or glass collisions are estimated to include 253 million wild bird mortalities at homes (structures under three stories) versus 339 million and 508,000 wild bird mortalities, respectively, at low-rise (4–11 stories) and high-rise structures (over 11 stories) annually in the United States alone.[2] The total estimates of mortality from collisions with human-made structures range from 365 to 988 million birds annually.[2]

Humans use reflections and building cues (door or window frames, openings, angles) to help determine where glass is located and to be avoided. While this does not prevent us from occasionally walking into glass panels or doors, it does help significantly reduce the incidence of human injuries. However, birds do not perceive glass in structures in the same manner.[3] Reflections of themselves can often make birds fly aggressively at glass as they perceive the other bird as a rival. Similarly, reflections of vegetation can lead to a bird trying to fly through the glass to the perceived vegetation on the other side. Even on overcast days, glass windows on adjacent walls at the corner of a building, or on opposite sides of a narrow hallway or corridor, may lead to a bird trying to fly through from one side to the other. Historical recommendations for reducing bird/glass collisions have involved the use of predator silhouettes, decals of various forms applied to windows, and placing material such as feathers or string behind or in front of the glass (Table 50.1). However, applying scare tactics with decals or even mock-ups of large predatory birds does not always work, as a bird may perceive that it can fly past or around the obstacle or threat, and still collide with the glass.

Recent scientific studies evaluated the effectiveness of deterrents and summarized the results of flying birds in tunnels.[3] Using tunnels for birds to fly through to test bird vision is a relatively new area of avian research. Budgerigars *(Melopsittacus undulates)* flying in such tunnels have demonstrated that birds have the ability to change wing position to maneuver through narrow spaces along their flight path.[4,5]

For passerine birds, the most common group involved in glass collisions, this means any opaque pattern on the glass must have a narrow spacing relative to the bird's morphometrics. The spacing for the pattern must be less than the body measurements of the bird so the bird will not be tempted to fold its wings in and squeeze through the opening.

The Max Planck Institute in Germany has developed a method of conducting glass avoidance trials with small birds.[6] In their research, recently captured (usually with mist nets) birds are released, with a choice of flying toward plain (control) or patterned glass windows. Injury to the birds is prevented by mounting another mist net in such a manner as to prevent collision with the glass in the test windows. Each bird is tested only once before being released back into the wild. A further refinement in this technique using a testing tunnel was developed at the Hohenau-Ringelsdorf Biological Station in Hohenau, Austria, in 2004.[7] A similar tunnel for testing is currently in use at the Carnegie Museum's Powdermill Avian Research Center, Rector, PA, USA.[3] The binomial choice protocols used at such facilities are a step toward developing a rating for various glass materials, reflective coverings or coatings, and deterrents.[3]

Recommendations coming out of these research centers are used for deterrent materials that can be applied to the outside surfaces of glass (Figures 50.1 and 50.2; VVivid Architectural Window Film Solutions, 3M, St. Paul, MN, USA; Note: any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the US Government). The outside surface of the glass is best for the deterrent so that the deterrent is not compromised by any reflections.[3] Deterrents applied to the inside surface can only be used if the outside surface has a low reflectivity.[3] The tunnel testing procedures of deterrents with passerines in Europe and North America appear to be consistent despite the differences of avian species, latitude, and longitude, indicating that such testing procedures are useful for evaluating various methods and materials to deter avian collisions with building glass.[3] Various jurisdictions in North America are beginning

TABLE 50.1

Listing of Various Modifications Used to Reduce Bird Collisions With Glass in Buildings

Design Feature	Evaluation
Building envelope	Overall extent of glass on outer building surface; bird strikes increase as ration of glass to solid wall increases. Buildings with 25%–40% total window surface reduce bird collisions.
Fly-throughs	Eliminate all potential fly-through conditions such as two windows perpendicular to each other at building corners, narrow corridors or bridges with glass windows on either side, and outdoor glass railings.
Awnings and overhangs	Awnings and overhangs can provide visual clues to birds about windows underneath. These features also help reduce reflected light.
Exterior screens, grills, shutters, or shades	All these elements reduce visible glass, thus reducing bird collisions. These devices can be used to retrofit existing buildings.
Visual markers	Visual markers or images on the glass surfaces give birds visual clues that the glass is a solid surface. The denser the pattern, the more effective a deterrent. Markers need to be high contrast, spaced 10 × 10 cm apart or less, be at least 5-mm diameter each, and be on the exterior glass surface to be most effective.
Nonreflective glass	Not as effective as some other methods when used alone but useful in combinations such as with visual markers.
Opaque glass, translucent glass, stained glass, glass block	Excellent options to let in light but reduce bird collisions. Reduced reflectivity while appearing as a solid object to birds.
Ultraviolet glass	Birds can see in the ultraviolet (UV) spectrum. Glass that reflects or absorbs UV light (300–370 nm wavelength) will appear solid to birds while appearing clear to the human eye.
Low-reflective glass	Mirrored glass is the most dangerous glass for birds. Low-reflective glass (less than 15% reflectance) reduces some types of bird collisions but needs to be combined with visual markers to be most effective.
Angled glass	Angling glass downward from vertical by 20–40 degrees has not been shown to be an effective deterrent to bird collisions.
Interior blinds, interior screens	Sometimes required to reduce bird collisions, these can be raised or removed by subsequent building occupants.
Tinted glass	No scientific evidence that tinted glass reduces bird collisions.
Bird (raptor) decals	Scientific testing has shown these decals as ineffective in reducing bird collisions. Only effective if applied in a pattern 5–10 cm apart over the entire window surface, in which case the decals are acting as visual markers (see Visual markers).

Table developed from the book *Bird-Friendly Best Practices – Glass*, City of Toronto. https://www.toronto.ca/wp-content/uploads/2017/08/8d1c-Bird-Friendly-Best-Practices-Glass.pdf. Accessed January 7, 2022.

FIGURE 50.1 Building at USGS Eastern Ecological Science Center that had a history of previous frequent bird strikes, especially the second-story center, where the hallway between the two wings of the building had glass on both walls. This picture shows the building after all windows were covered with a film (VVivid Architectural Window Film Solutions, 3M, St. Paul, MN, USA) to deter birds from striking the glass. (Photograph by the author.)

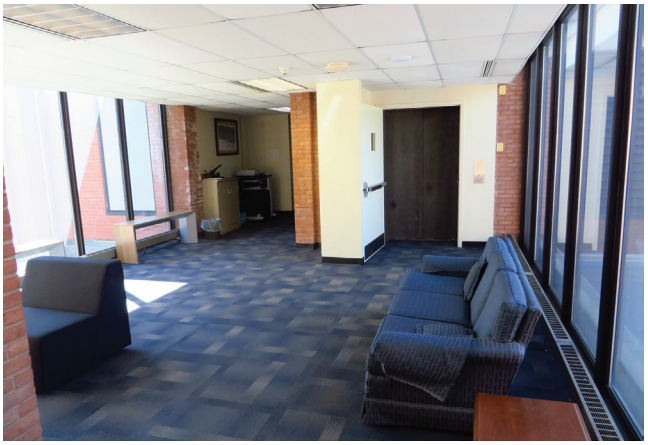

FIGURE 50.2 An inside view of a glass-lined hallway at USGS Eastern Ecological Science Center, Gabrielson Laboratory, that had a history of frequent bird collisions. This view is after a film (VVivid Architectural Window Film Solutions, 3M, St. Paul, MN, USA) was placed on outside window surfaces to deter bird collisions. (Photograph by the author.)

to require bird-friendly glass (glass that reduces or eliminates collisions) to be installed on new buildings and during major renovations of older structures. New York City recently passed legislation requiring new buildings and those undergoing major renovations meet bird-friendly standards to reduce bird strikes.[3]

NOISE

Anthropogenic noise sources can be a problem for some avian species. Noise can mask communications among members of a species, displace birds from breeding or foraging habitat, disrupt predator-prey interactions (e.g., owls hunting by sound at night), impact mate selection, and may cause injury to bird hearing.[8] Physiological responses to exposure to noise may include hearing threshold shifts, hormonal changes, and even tissue injury. Interestingly, noise may facilitate nesting success in some species as a result of the disruption of predator-prey dynamics.[9] A study in northwestern New Mexico, USA, evaluated the influence of noise on nesting community, nest density, and nesting richness in woodland habitat adjacent to natural gas wells with noise-producing compressors ("treatment") versus those that lacked noise-generating compressors ("control"). In this study, they found that noise reduced nesting by a major avian nest predator, the western scrub-jay *(Aphelocoma californica)*. However, with reduced use of the higher noise areas by the western scrub-jay, fewer nests of other species were predated, resulting in a positive effect on nesting success.[9] Nests were also significantly less parasitized by the brown-headed cowbird *(Molothrus ater)* in the noise-polluted sites as compared to control sites ($P = 0.003$).[9] However, the study also found that noise levels reduced nesting community species richness from 32 species at control sites to 21 species at high noise level sites ($R = 0.19$, $P \leq 0.001$).[9] These findings indicate that certain bird species are much less tolerant of noise pollution, resulting in a shift in species diversity in noise-polluted areas.[9]

Forest birds largely use vocalizations to communicate with one another. Typically, these vocalizations are in the range of 1.5 to 4.0 kHz, which coincides with anthropogenic machinery noise.[10] If noise from anthropogenic sources competes with male bird songs used to attract mates, then the birds in the area with noise pollution could be less likely to attract a mate, or, alternatively, the noise-polluted area could be less desirable as a breeding territory. One study examined the noise produced by compressor stations along oil and gas pipelines in the boreal forests of Alberta, Canada.[10] The authors found 92% of male ovenbirds *(Seiurus aurocapilla)* at control sites (no machinery noise) successfully paired versus only 77% ($P = 0.02$) at the noise-polluted compressor sites.[10] The noise-polluted sites were less often chosen by older adult ovenbirds (after second year [ASY]). Male ASY ovenbirds were found at 70% at control sites versus only 52% ASY male ovenbirds at noise-polluted compressor sites.[10] The reduced pair formation and, thus, nesting success of the ovenbirds at the noise-polluted sites may be attributed to the male ovenbird vocalizations not being heard or being less effective because of the background machinery noise. This study suggests that other songbird species may likewise be negatively impacted by anthropogenic noise. Other effects of anthropogenic noise can include reduced ability to detect (hear) predators approaching, changing the frequency of song to avoid the frequency of the anthropogenic noise, and the sounds made by nestlings not being heard, resulting in decreased feeding and increased nesting mortality.[10]

Another study of anthropogenic noise on wild birds in the Rattlesnake Canyon Habitat Management Area (Bureau of Land Management), New Mexico, USA, found that with western bluebirds *(Sialia mexicana)*, mountain bluebirds *(S. currucoides)*, and ash-throated flycatchers *(Myiarchus cinerascens)* there was a consistent pattern of hypocorticism in response to increases in noise amplitude.[11] This study found decreased fitness in the form of hatching success, reduced body condition of the hatched chicks, reduced feather growth (with noise levels above 70 decibels [dB]), and reduced body size of fledglings (also with noise levels above 70 dB).

In the Netherlands, a similar association between age, pairing status, and anthropogenic noise has been identified in willow warblers *(Phylloscopus trochilus)*. In this study, however, the anthropogenic noise source was automobile traffic, and the noise affected willow warblers for distances up to 200 m from the highway.[12] The US Geological Survey's Breeding Bird Survey (BBS), which is conducted each year along multiple roadside locations, also indicates that automotive noise levels along roads may lead to diminished use of the nearby habitat for breeding by many other songbird species.[13] This could be interpreted as a population decline of breeding birds in those roadside areas but may also represent an avoidance of the roadside area due to the increase in anthropogenic highway noise rather than a habitat-wide decline in species numbers.[13]

Hearing capability has been measured in about 50 of the 10,000 species of birds worldwide.[8] Many studies measure hearing ability of birds in laboratory settings or quiet field settings, while underwater hearing has been measured for a few bird species that spend most of their lives in/on water. These include penguins, gannets, sea ducks, auks, and a few other species. Sounds travel further underwater than in air and, therefore, can impact birds over a greater area. Some of the anthropogenic noises in the underwater environment (Figure 50.3) that could negatively affect sea or diving birds include propeller noise from boats and ships, construction noise, sonar activities from naval vessels, and the thrumming sounds of wind turbines transmitted down the pylon into the water.

Recently, diving bird hearing has been measured by both behavioral audiograms and auditory brainstem response (ABR), both in the air and underwater.[8] Typically, ABRs were compared to the spectrographic analysis of vocalizations for each species. The dominant vocalization frequency corresponds well with the frequency of best hearing (1–2 kHz; Figure 50.3) in most species, except the common eider *(Somateria mollissima)*. The vocalizations of common eider (0.44 kHz) were significantly lower than their frequency of best hearing (2.4 kHz).[14] Also, northern gannet *(Morus bassanus)* had comparatively poor hearing, second only to the common eider. Both species are colonial nesters, and their hearing possibly reflects their need to communicate only across short distances in a crowded breeding colony.[8] This lower hearing threshold in these two species may give them some additional protection against noise disturbance in their environment.[8]

The waterfowl species with the most sensitive hearing among the tested bird species were the lesser scaup *(Aythya affinis)* and the ruddy duck *(Oxyura jamaicensis)*.[8] These two

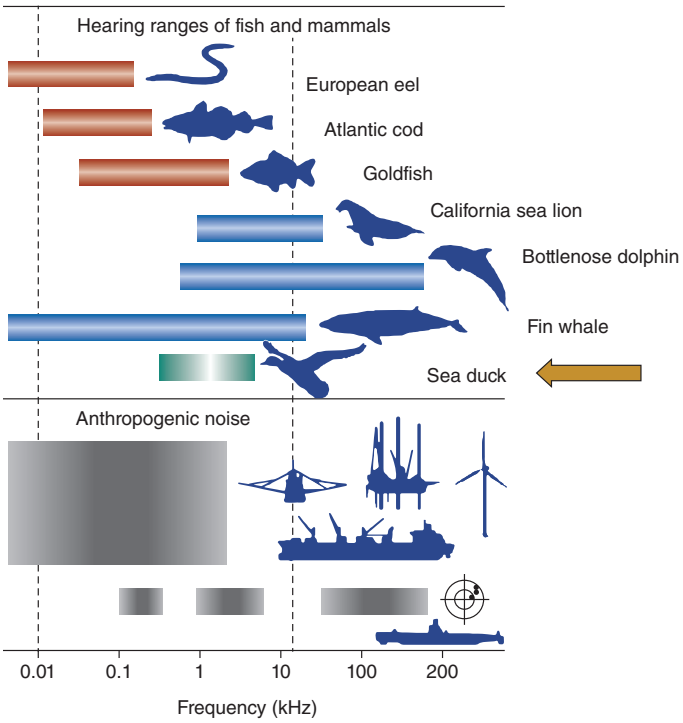

FIGURE 50.3 Hearing ranges for various animals and examples of aquatic noise relative to data collected on sea ducks. (Modified by Alicia Berlin, adapted from Slabbekoorn H, Bouton H, van Opzeeland I, et al: A noisy spring: the impact of globally rising underwater sound levels on fish, *Trends Ecol Evol* 25(7):419–427, 2010, used with permission.)

species are more often found in inland, freshwater environments that tend to be quieter than the coastal and marine habitats where wind and waves create noises. Since their hearing is most sensitive, the potential adverse impact of introduced anthropogenic noise would likely be highest for these two species. In freshwater habitats, which represent their habitat, boat traffic, construction, locating wind turbines, etc., should therefore be avoided or minimized, if possible.

ELECTRIC LINES/POWER GRID COLLISIONS

Two subsets of the electric power networks are especially troublesome for birds, that is, electric power lines and wind turbines. Concern for the detrimental effects of the electric power production grid on avian species has grown over the years. Most recently, this concern has expanded even further as wind turbines are sited with increasing frequency across the landscape (see section on Wind Turbines).

Power line or transmission line collisions and electrocutions are primarily a problem for larger bird species, including swans, cranes, and large birds of prey. To reduce power line collisions, the utility companies, the US Fish and Wildlife Service (USFWS), and the National Audubon Society, along with the University of Idaho and Clemson University, Clemson, SC, USA, created the Avian Powerline Interaction Committee (APLIC) in 1989. According to the APLIC, there are over 804,500 km (about 500,000 miles) of bulk transmission lines in

FIGURE 50.4 A dead sandhill crane *(Antigone canadensis)* found under a powerline in the Platte River Valley in Nebraska. Such findings are frequently seen in the spring when sandhill cranes and whooping cranes *(Grus americana)* use the fields adjacent to river roost sites and often fly into or from the fields in low light conditions at dawn or dusk. (Photograph by the author.)

the United States alone.[15] In addition, these electrical lines have nonconducting ground wires installed above the conducting wires, to mitigate lightning strikes that would otherwise cause power outages. These ground wires are the ones most often hit by low-flying birds as these are smaller (0.9–1.3 cm diameter) and therefore less visible than the conducting wires.[16,17] Large birds are either injured by the collision or found dead under the wires due to crashing into the ground following the collision (Figure 50.4). Estimates of avian power line mortality in the United States range up to 175 million birds annually.[17] One author[18] observed 7000 flights of various types of birds over a power line in North Dakota, USA, and counted about 1% of the birds colliding with the lines. He estimated 124 fatalities/km/year. In North America, 36% of juvenile sandhill crane *(Antigone canadensis)* mortality is attributed to power line strikes.[16] The mortality rate for red-crowned cranes *(Grus japonensis)* in Japan was 2.1% for adults and 13.4% for juveniles. Mortality from power line strikes comprised 44% of total mortality for juvenile trumpeter swans *(Cygnus buccinator)* in Wyoming, USA.[19] For Dalmatian pelicans *(Pelecanus crispus)* in Europe, the estimated mortality from power line strikes varied from 1.3% to 3.5%.[17,20] Power line strike mortality can become a biologically significant factor for small, endangered bird populations. As an example, whooping cranes *(Grus americana)*, which number less than 800 birds in the wild in North America, had a mortality rate of 12% from power line collisions in the Florida Nonmigratory Population, 17% of all mortality in the Eastern Migratory Population, and 39% of all mortality in the now extirpated Rocky Mountain Population.[17] For the largest migratory flock of whooping cranes, the Aransas-Wood Buffalo population, which migrates between northeastern Alberta, Canada, and the Texas Gulf Coast, USA, estimates of

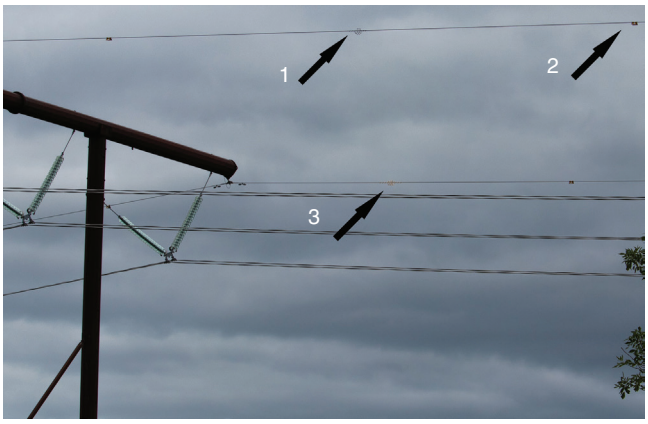

FIGURE 50.5 Three different bird flight diverters attached to power lines. *Arrows 1* and *3* are pigtails: *3* is yellow and *1* is gray. *Arrow 2* is the Powerline Sentry marker (Power Line Sentry, Wellington, CO, USA). "Hannah Jones/International Crane Foundation"

total mortality caused by power line collisions varies from 33% to 38%.[21]

Power line collisions can be related to weather conditions. Weather that causes reduced visibility (fog, precipitation, low-light conditions) or reduced maneuverability (high winds) increases the chances of a power line collision. To address concerns for these detrimental effects, power lines in areas frequented by large birds, such as wetlands and foraging areas, can be equipped with markers of high-impact polyvinyl chloride in shapes that enhance the visibility of the power line to the birds.[15] These methods include aerial marking spheres as commonly seen on power lines near airports. Other markers, including spiral vibration dampers, bird flight diverters, and swan flight diverters (Figure 50.5), have been used and shown to significantly reduce collisions.[17] Other recommendations are to (1) monitor placement and design of new power lines, avoiding areas within 2 km of roosting or foraging sites, where possible; (2) remove unnecessary power lines from areas frequented by large avian species; (3) bury new, and in some cases, older, distribution lines; and (4) use yellow-colored markers as these may be more visible to birds, especially in low-light conditions.[17] Markers on power lines have been shown to reduce bird mortality by 57% to 89% in the Netherlands,[22] 53% for nonpasserines species in South Carolina, USA,[23] and 61% to 63% for cranes and waterfowl in Colorado, USA.[24] As the use of these markers on power lines is relatively inexpensive and can be targeted for areas known to be sites of avian mortality incidents, use of these should be encouraged.

WIND TURBINES

The increased demand for affordable "clean" energy sources has expanded the use of wind turbines around the world. In the United States in the last 15 years, over 59,000 land-based wind turbines have been built in 41 states, Guam, and Puerto Rico.[25] However, wind turbines can frequently pose a threat to avian species. It is important to understand these threats and to develop feasible and cost-effective plans to minimize adverse avian events.[25]

The location of wind turbines can adversely affect raptors and other large species, which may collide with the rotating blades. The Altamont Pass Wind Resource Area in California, USA (37°43′57″N, 121°39′9″W) has caused 28 to 68 golden eagle *(Aquila chrysaetos)* collision mortality events annually.[25] These high rates of collision fatalities have only been recorded at a few wind turbine sites. The raptor species adversely affected also vary by site. Modeling has been used to try to predict potential mortality of raptors at wind turbine sites. Such modeling techniques utilize the hazardous footprint of the facility, bird exposure to the wind turbines, and collision probability.[26]

In Europe, offshore wind production has grown rapidly.[27] The United States has lagged far behind Europe in offshore wind turbine placement, with only five wind turbines operational off Block Island, RI, USA, in 2020. The rapid siting of wind turbines offshore in Europe and increased interest in such facilities in the United States has spurred the interest in studying possible effects on marine wildlife.[27] For avian wildlife, this includes collision mortality, habitat loss from avoiding wind turbine areas, possible barriers posed by wind turbine arrays to efficient migration, and increased energy expenditure by birds when avoiding these areas. Unlike land-based wind turbines where searches for avian carcasses in the vicinity of wind turbines is an established technique, counting mortalities from offshore wind turbines is very difficult. In Europe, studies before and after wind turbine construction have demonstrated avoidance behavior after the establishment of wind turbines.[27] Meta regression analysis of multiple wind farm studies shows that Anseriformes and Charadriiformes are the most negatively impacted.[28] According to this study, population numbers of long-tailed ducks *(Clangula hyemalis)*, common eider, and common or black scoter *(Melanitta nigra)* should be considered most vulnerable to negative impacts of wind farms.[28] However, not all bird species are necessarily displaced by offshore wind farms. In one study in Belgium,[29] northern gannets *(Morus bassanus)*, common guillemots *(Uria aalge)*, and razorbills *(Alca torda)* were found in significantly decreased abundance (85%, 71%, and 65%, respectively) after construction of an offshore wind farm. However, lesser black-backed gulls *(Larus fuscus)* and herring gulls *(Larus argentatus)* numbers increased significantly. Similarly, the numbers of other gull species increased, but not by significant numbers. Based on these findings, the authors speculate that offshore wind farms may offer gulls increased roosting or feeding opportunities.[29] Falconiformes, Accipitriformes, and Passeriformes also appear less negatively impacted by wind farms.[28] Nevertheless, studies of the impact of wind farms on birds thus far fail to identify if the wind farm results in an overall decline in bird populations or a decline in use due to avoidance and therefore shift to using other areas.[28] Similarly, no study has looked at the overall possible negative impact of wind farms on birds versus the negative impact of climate change from continuing to burn fossil fuels to generate electricity.

In the United States, the Federal government has jurisdiction over waters beyond three nautical miles (5.6 km) where wind turbines would be placed. During the past 10 years, the Department of Interior, Bureau of Ocean Energy Management, has funded aerial- and boat-based surveys to document marine birds in coastal waters.[27] In addition, a multiyear tracking study using satellite telemetry has focused on three key species, that is, northern gannets, red-throated loons *(Gavia stellata)*, and surf scoters

(Melanitta perspicillata).[27] All three species use the Atlantic coastal waters as their habitat for 7 months of the year (October–April) and stay within 5 km of the coast, except when migrating along the coast where there are large estuarine incursions (e.g., the openings of Chesapeake Bay and Delaware Bay).

Wind turbines are frequently located in the Great Plains, habitat to grassland bird species. Grassland birds suffer from many anthropocentric disturbances. The greatest disturbance has been the conversion of much of their native grassland habitat to row-crop agriculture. New energy development has added another source of habitat loss for this group of birds. Large sections of the prairies, starting in Illinois and Indiana, USA, and now continuing in Wyoming and other western states, have been permanently altered by strip mining for coal, primarily used in electric power generation. Other areas of the prairie, such as in Texas, USA, have experienced changes with the development of the oil industry with noise pollution, construction of roads bisecting prairie habitat, etc. Now new wind farms composed of aggregates, multiples or even hundreds of wind turbines, have permanently altered the prairie habitat, as have solar energy arrays.[25] In the Great Plains and Inter-mountain West, large developments such as these degrade habitat quality, increase noise levels, increase roads that are used by large vehicles, alter predator populations and use (roads increasingly used as predator travel corridors), and allow the introduction of invasive plants that replace the native plants whose seeds the grassland birds rely upon.[26]

OTHER ENERGY-RELATED ANTHROPOCENTRIC AVIAN WILDLIFE CONSIDERATIONS

Energy infrastructure and development can have less lethal effects on avian species than would be seen with power line or wind turbine collisions. Birds are common in most landscapes. Changes in these landscapes to accommodate energy infrastructure can lead to changes in avian behavior and even population declines.

Lesser prairie chicken *(Tympanuchus pallidicinctus)* populations in Colorado, New Mexico, Kansas, Oklahoma, and Texas have suffered population declines tied to habitat loss, caused by grassland to cropland conversion and energy development.[25,30] A major factor in grassland to cropland conversion in recent years has been the development of center-pivot irrigation systems, made possible by cheap energy and the development of transmission and distribution lines, to bring this electric power to evermore remote stretches of land. Researchers have documented the avoidance behavior of some species of grassland birds around energy production sites.[25] This has led to the development of decision-support tools that can be used for conservation decision-making and justification for compensatory mitigation in the form of prairie land purchases and preservation.[31]

Whooping cranes migrate along a 2500-mile corridor from the Texas (USA) Gulf Coast at Aransas National Wildlife Refuge to the Wood Buffalo National Park in northeastern Alberta, Canada. During this migration, they not only encounter increasing numbers of electrical transmission and distribution lines, but now also must avoid arrays of wind turbines and hundreds of square kilometers of severely disturbed habitat in the form of the Canadian oil sands mining area immediately south of their breeding grounds in Alberta. Indeed, radio telemetry studies have shown that the whooping cranes fly over this area on both northward and southward migratory trips without stopping at any rest areas. When birds must modify migration routes to avoid areas, this requires more energy to make the migration and may require stopover sites in unfamiliar territory or longer stopovers to meet energy demands for longer migration flights. Such changes can lead to predation in unfamiliar territory or reduce nesting time once arriving on the breeding grounds.

Dams to produce hydroelectric power can also permanently alter avian habitat. Loss of large stretches of natural habitat along the Missouri River in the central USA has adversely affected species such as piping plover *(Charadrius melodus)* and least tern *(Sternula antillarum)* that use the riverine sandbars as nesting habitat. Now the US Army Corps of Engineers, responsible for the dams and the river, is starting to create suitable nesting habitat for these birds as part of the Missouri River Recovery Program.[25]

CHAPTER 51

Petroleum Products

Karyn Bischoff • *Kendal E. Harr*

Visit **eBooks.Health.Elsevier.com** for a complete set of references

INTRODUCTION

Many substances fall into the category of petroleum products, from extracted crude oils to heavy fuel oils and other distillation products. Crude oil is a complex mixture that can include long straight-chain hydrocarbons, short-chain (10 carbons or fewer) hydrocarbons that can be saturated (alkanes) or unsaturated (alkenes), branched hydrocarbons, aromatic hydrocarbons including polycyclic aromatic hydrocarbons (PAHs), sulfur-containing compounds, and heavy metals.[1] Crude oil composition, and thus its toxic properties, varies between and within sources, over time due to weathering, and with commercial processing, due to addition of compounds to improve commercial characteristics.[1] Weathering may result in evaporative loss of more volatile compounds, photooxidation and polymerization, biodegradation, dissolution, and emulsion in water.[1–4] Variation of specific toxicants in petroleum products results in a wide variety of toxic effects in birds and other animals, including humans. Long-chain hydrocarbons, such as those in mineral oil, act as a cathartic and decrease gastrointestinal (GI) transit time, thus affecting hydration and electrolyte status through GI losses and directly inhibiting absorption of some fat-soluble nutrients. Short-chain hydrocarbons and smaller PAHs, as found in gasoline and kerosene, are volatile and increase the risk of direct damage to alveolar membranes due to inhalation or aspiration after oral exposure but are lost quickly due to weathering.[1,2] Larger PAHs, which are components of coal and tar, remain in weathered oil, becoming relatively concentrated.[1,5]

Spills of petroleum compounds (oil spills) are reported worldwide. Since 1907, there have been more than 140 large oil spills (>30 metric tons or ~210 barrels) that have released more than 7,000,000 metric tons (about 49,000,000 barrels) of oil into the environment.[3] These numbers do not include the countless smaller spills, which often remain undocumented.[4] Approximately 1,300,000 metric tons (about 9,100,000 barrels) of petroleum enter the world's oceans every year, including 260,000 metric tons (~1,820,000 barrels) from North America. About 45% of the worldwide input is due to natural release, 37% is associated with consumption (cars, boats, runoff from urban areas), 11% is due to petroleum transport, and 3% due to extraction activities.[6] Thousands of oil spills are reported annually in the United States, and although most are small, there have been at least 44 recorded oil spills that have released at least 1500 tons (about 10,500 barrels) of oil.[7] Since 1970, the largest international oil tanker spills on record are the 1979 Atlantic Empress spill in the West Indies (287,000 metric tons, more than 2 million barrels), the 1991 ABT Summer spill off Angolan coast (260,000 metric tons), the 1983 Castillo de Bellver spill near the South African coast (252,000 metric tons), and the 1978 Amoco Cadiz spill off the coast of France.[8] There are numerous Asian spills, which are often poorly reported in the United States, including the Sanchi spill in the East China Sea (136,000 metric tons, around 1 million barrels).[8] The Exxon Valdez in Prince Edward Sound, Alaska, by comparison, spilled 37,000 metric tons (~260,000 barrels) of oil.[8] Oil spills reported in the United States can be searched at https://incidentnews.noaa.gov/.

The largest accidental oil spill documented is the BP Deepwater Horizon (DWH) spill, which released more than 650,000 metric tons (over 4.5 million barrels) of oil into the Gulf of Mexico.[9,10] The DWH oil spill began on April 20, 2010, with an explosion and fire at the DWH drilling unit off the coast of Louisiana, killing 11 workers and injuring another 17. Oil release from the DWH drilling unit was uncontrolled for nearly 3 months, covering more than 100,000 km^2 of the surface of the Gulf of Mexico and at least 1700 km of shoreline in Louisiana, Mississippi, Alabama, and Florida.[11] The spill killed countless wildlife, including tens of thousands of adult and fledgling birds, as well as decimating the next year's recruitment. More than 3500 birds were seen visibly oiled and 8500 dead birds, including at least 93 different species, were found.[9]

Because oil spreads over aquatic surfaces and persists for a prolonged period, marine and freshwater aquatic birds that make the water surface their habitat are particularly susceptible to oiling.[1] However, other avian species may also be affected; for example, aquatic birds and other organisms are fed upon by birds of prey, and animals debilitated by oiling are more likely to be predated.[12,13] Since many birds migrate thousands of miles, a single point source can have far-reaching effects on other food chains.[13]

Heavy oiling of birds can be rapidly lethal due to both effects on plumage and systemic toxicosis. Multisystemic pathology, affecting GI, cardiovascular, renal, and immunologic function, can result from exposure to low doses of crude oil and other petroleum products and result in mortality.[9] Oiling furthermore causes considerable stress in birds, as does retrieval, cleaning, and captivity of oiled birds. While birds may be rehabilitated after exposure to lower doses,

there are detrimental effects to both egg production and hatch rate with subsequent potential to negatively impact populations, especially those that are small.[14–17] There are also significant differences in species susceptibility to oil toxicosis due to anatomic, physiologic, behavioral, and life history factors.[18] Birds that frequent an aquatic habitat are at higher risk of exposure than passerine birds, for example. Oiled pelagic birds in more temperate and arctic climates are more likely to experience depletion of energy reserves to maintain body temperature than those in more tropical climates. Among birds associated with aquatic habitats, birds that are calmer around humans, such as penguins, are more likely to survive past rehabilitation than shore birds that are anxious and stressed in captivity.

Environmental effects of individual oil spills continuously impact birds and other wildlife for many decades. Oil spills essentially sterilize beaches, killing corals and invertebrates in sediments, thereby causing long-term food chain effects. Spills destroy habitat by killing marshland plants and changing microbial populations in soils and sediments, leading to increased shoreline erosion.[10,11] Coastal mangroves, for example, prevent coastal erosion and provide important nutrients and habitat, including breeding habitat, for many species in the marine food chain. Recovery of mangrove forests and salt marshes takes decades.[12,11] Plants, fish, and invertebrates that have survived oil spills or repopulated damaged areas are continually exposed to residual petrochemicals, possibly leading to long-term impacts on aquatic food webs.[4,11] A study of seaside sparrows *(Ammodramus maritimus)* from the US Gulf Coast noted increased CYP1A5 enzyme activity, related to PAH exposure, in 2013 after Hurricane Isaac redistributed oil deposited from the 2010 DWH spill.[11]

Attempts to remediate oil spills also bring a host of problems. In situ burning, which attempts to remove oil by combustion, converts petroleum to products such as carbon dioxide, water, soot, and so on.[19] Though combustion may decrease exposure of marine birds to residues, experimental results suggest that combustion products may cause more feather damage than the original oil.[19]

Chemical dispersants, composed of mixtures of surfactants, organic solvents, and petroleum products that cause smaller droplets of oil to form in the water column, have been used to redistribute oil from the surface of water deeper into the water column, hence potentially expediting oil decomposition.[20,21] However, there are significant differences in the chemical composition of dispersants, and their toxicity must be individually evaluated. For example, Corexit 9580 is predominantly composed of petroleum distillates (volatile petroleum products), whereas Corexit 9500 has up to 30% petroleum distillates, and Corexit 9527 does not contain any petroleum distillates, based on manufacturer information.[22] Dispersants not only reduce the surface tension of the water, they bind to feathers, allowing water to pass into plumage and causing experimental eider ducks *(Somateria mollissima)* and murres *(Uria aalge)* to become waterlogged; the decreased ability to float could potentially lead to drowning deaths.[19,20] Additionally, the use of organic solvents to disperse oil results in increased bioavailability of previously hydrophobic oil particles, as well as deeper dispersion into sediments.[23,24] This results in increased measurable toxic effects in vertebrates, including sea turtles, when oil and Corexit are applied together. While this has not been explored in birds to the authors' knowledge, similar effects are expected. It is important to note that, while Corexit is currently listed on the website of the Environmental Protection Agency (EPA) as "nontoxic," evaluation of the EPA's toxicity table reveals that the Corexit 9500 and oil combination (which is the only composition relevant to field settings) has two to three times the acute toxicity as the reference toxicant, sodium dodecyl sulfate (Table 51.1).

TABLE 51.1

Toxicity of Corexit 9500

EPA-REPORTED TOXICITY DATA FOR INLAND SILVERSIDE FISH *(MENIDIA BERYLLINA)* AND MYSID SHRIMP *(MYSIDOPSIS BAHIA)*

Material Tested	Species	LC_{50} in ppm (mg/L)/time to reach 50% lethality
Corexit EC9500A	*Menidia beryllina*	25.20/96 hours
	Mysidopsis bahia	32.23/48 hours
No. 2 fuel oil	*Menidia beryllina*	10.72/96 hours
	Mysidopsis bahia	16.12/48 hours
Corexit EC9500A and No. 2 fuel oil (1:10)	*Menidia beryllina*	2.61/96 hours
	Mysidopsis bahia	3.40/48 hours
Reference toxicant (sodium dodecyl sulfate)	*Menidia beryllina*	7.07/96 hours
	Mysidopsis bahia	9.82/48 hours

LC_{50}, Median lethal concentration.

ACUTE EFFECTS OF PETROLEUM PRODUCTS

External Oiling

External oiling is the most common form of oil exposure in birds, causing the majority of sea bird mortality and producing a number of detrimental effects.[19,25] Feathers serve important roles in flight, insulation, and, in pelagic and aquatic birds, buoyancy.[1] Even small amounts of crude oil disrupt feather structure, collapsing hooks, barbs, and barbules and affecting functionality.[25] Oiled birds also pluck feathers while preening, further disrupting the protective properties of the plumage.[26] Consequently, oil ingestion results from normal preening behavior.[25,27] Oiling can be very difficult to identify in brown birds, and underreporting of darker birds in comparison to light or white birds was documented in field reporting during the DWH oil spill (Figure 51.1). Instead of visually inspecting darker birds, it may be easier to identify potential oiling by smell, especially at distance.

Oiled feathers lose the ability to insulate and trap air, causing decreased buoyancy and allowing cold water to reach the skin. Oiled birds in cold climates can die rapidly from the resulting hypothermia.[9,27] Even in warmer climates, oiling decreases birds' thermoregulatory capabilities.[9,28] Poor thermoregulation leads to

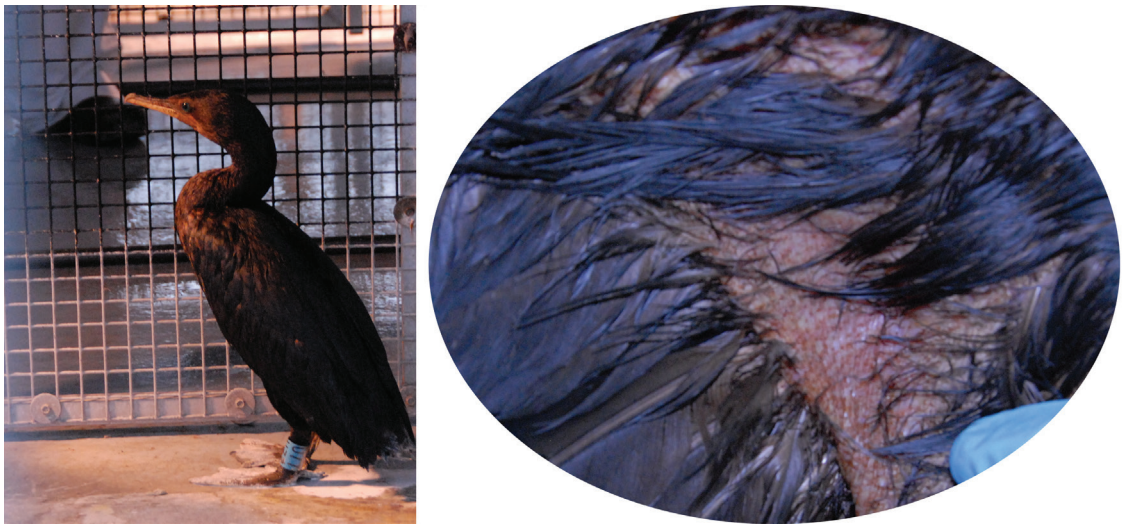

FIGURE 51.1 Cormorant (*Phalacrocorax* spp.) with <15% coverage of oil (approximately one tablespoon) applied to breast every 3 days for six total applications. It is difficult to see the oil on the brown bird at any distance even when the bird is standing in the light. Closer inspection of the axillary region *(right)* reveals significant oiling with compromised feather integrity that negatively impacts flight and allows heat loss.

increased energy demands for heat production and preening. When combined with decreased food availability, decreased time available, and decreased foraging efficiency, weight loss occurs. This, in turn, decreases reproductive and migratory capabilities.[9,28]

Oiling affected flight performance in experimental homing pigeons *(Columba livia)* and western sandpipers *(Calidris mauri)*.[25,29–31] Oiling significantly increased the time it took pigeons to travel a set distance for a month after application, mostly due to the pigeons' inability to sustain flight.[29] Sandpipers experimentally oiled with weathered MC252 had reduced take-off speed, lowered take-off angle, and flew shorter distances than controls, which would negatively influence their ability to escape predators and complete their annual migration across continents.[27,31] Experimentally oiled homing pigeons experienced increased weight loss and failed to recover the weight as quickly as control birds, possibly due to increased energy expenditures for flight and thermoregulation as well as toxic effects of preened oil on the GI tract.[25] The slowing or delay of migration due to feather damage and weight loss is likely to impact survival and reproductive capacity.[29,30]

Gastrointestinal Effects

Birds ingest oil in contaminated food and water and by preening oiled feathers. Oil ingestion during and after an oil spill is likely to occur over days to weeks.[1] Long-chain hydrocarbons have a cathartic effect when ingested; diarrhea and decreased nutrient absorption result.[32] Decreased specific nutrient absorption, including glucose transport, was noted in experimentally dosed herring gulls *(Larus smithsonianus)*.[33] Over time, these changes can lead to reduced body condition.[9] However, the cathartic action also leads to rapid elimination, which is hypothesized to decrease absorption and may reduce systemic effects of oil ingestion.[5,34] Irritation of the GI tract was associated with regurgitation in pigeons and murres.[18,35] GI hemorrhage and regurgitation were reported in oiled murres entering rehabilitation, and many birds that survived bathing later developed skin and leg lesions and respiratory problems.[35] Regurgitation increases the risk of aspiration of volatile hydrocarbons, leading to lipid pneumonia.

Pulmonary Effects

Lipid pneumonia can occur in heavily oiled birds from inhalation of oil droplets and aspiration of regurgitated, oil-contaminated material.[1] While respiratory effects were not a targeted, quantified end point of the United States Fish and Wildlife Service (USFWS) avian toxicity study, researchers noted dyspnea in orally and dermally exposed cormorants (*Phalacrocorax* spp.) while normal respiratory function was maintained by control birds throughout the study.[36] The weathered MC252 oil used in the study had significantly reduced volatile petroleum products in comparison to unweathered crude oil and, therefore, birds could have markedly increased respiratory damage when exposed to other crude oils or distillates.[2,37,38]

Neurologic/Sensory Effects

Oil exposure is associated with lethargy and obtundation in birds.[26] Cormorants dosed with artificially weathered MC252 oil, either orally or via external dosing, were lethargic. In addition, those with oral dosing kept their heads under their wings and were anorexic and unresponsive to external stimuli.[26]

Ocular damage has been reported in murres experimentally exposed to oil, dispersant, and oil plus dispersant.[21] Affected birds had conjunctivitis and many developed corneal ulcers and anterior uveitis, which in turn can affect foraging and predator evasion behavior and can lead to permanent vision loss.[21]

Reproductive/Embryotoxic Effects

Nesting birds that become even mildly oiled will transfer oil from breast feathers or feet to the surface of their eggs.[1,39] Even microliter (μL) quantities of oil on the eggshell can lead to embryonic defects, reduced egg hatchability, and increased mortality prior to fledge.[1] A study on weathered DWH crude

oil on mallard duck *(Anas platyrhynchos)* eggs found a median lethal dose of 31 μL/egg or 0.5 μL/g, though much lower lethal doses have been reported from other oil sources.[39] Absorption of PAHs through the eggshells is the most likely cause of embryonic deaths and explains the difference in toxicity between crude oil and weathered crude oil.[1] Postmortem examination of fresh embryos and hatchlings may reveal liver necrosis, renal degeneration, and generalized edema or no identifiable gross or histopathologic lesions at all.[1] Chicken eggs exposed to airborne volatile compounds from DWH crude oil had embryonic changes; volatile compounds, predominantly benzene, toluene, xylene, and ethylbenzene, caused thrombocytopenia, increased plasma osmolality, and increased CYP1A expression across several tissue types in embryonic chicks.[40]

Birds surviving oiling can have reduced egg laying, egg viability, and hatchability, possibly related to endocrine disruption.[1] Behavioral changes in the parents can be a potential cause of reduced hatchability, but structural effects on the egg, such as reduced shell thickness and yolk composition, were also reported.[41] There is evidence that oiling survivors can return to reproductive success.[1,42,43] Though there was reduced hatching success in rehabilitated little blue penguins *(Eudyptula minor)* the first season after release, no differences were detected in egg laying, hatching, or fledging success in subsequent seasons.[43]

SUBACUTE TO CHRONIC EFFECTS OF PETROLEUM PRODUCTS

Cardiovascular Effects

Chronic low-dose dermal exposure to artificially weathered MC252 oil (less than three tablespoons over 3 weeks) was associated with cardiac arrhythmias, including bradycardia and tachycardia, in cormorants.[44] No histologic changes were noted, but the hearts of both cormorants and laughing gulls *(Leucophaeus atricilla)* appeared flaccid on necropsy (Figure 51.2).[44,45] Echocardiography on oil-exposed cormorants indicated decreased systolic function and decreased left ventricular stroke volume, suggestive of dilative cardiomyopathy.[36] Cardiac isoform troponin I was elevated above the cormorant reference interval (<0.015 ng/mL) in all oil-exposed birds, indicating myocardiocyte damage.[46]

Hematologic Effects

Oxidative damage to erythrocytes, leading to Heinz body hemolytic anemia, has been reported in many avian species exposed to petrochemicals.[1,5] Even pelagic birds recovered from spill areas with no visible oiling are reported to have increased numbers of reticulocytes and Heinz bodies.[9,45] Heinz bodies were identified within 4 to 7 days of oral or dermal exposure, although erythrocyte damage can be evident already within 2 days following exposure.[1,5,32,47] However, avian erythrocyte morphology makes Heinz bodies difficult to identify by light microscopy and evaluation using electron microscopy is recommended (Figure 51.3).[47] The classic button-like, cytoplasmic projection that typically indicates Heinz body anemia in mammals does not occur in birds, even in blood samples from birds with biomarkers indicating severe oxidative damage. Therefore to use Heinz bodies as a biomarker for petroleum exposure in the field, a small amount of blood should be preserved in 2% to 3% buffered glutaraldehyde and immediately refrigerated (kept in a cool dark place). Electron microscopy specimens must be sent to a facility and technologist with experience in processing and examining blood samples. Contact a veterinary diagnostic laboratory for further information on avian cytology.

Epoxides directly interact with sulfhydryl groups on hemoglobin leading to hemoglobin precipitation in erythrocyte cytoplasm forming Heinz bodies.[47] Weakening of erythrocyte cell membranes secondary to oxidative damage, as well as the physiologic response to erythrocyte damage, culminates in hemolysis.[5] Reticulocytes (immature red blood cells) are released into circulation to compensate for erythrocyte loss, resulting in increased reticulocyte concentrations. However, this mechanism may not be sufficient to compensate for

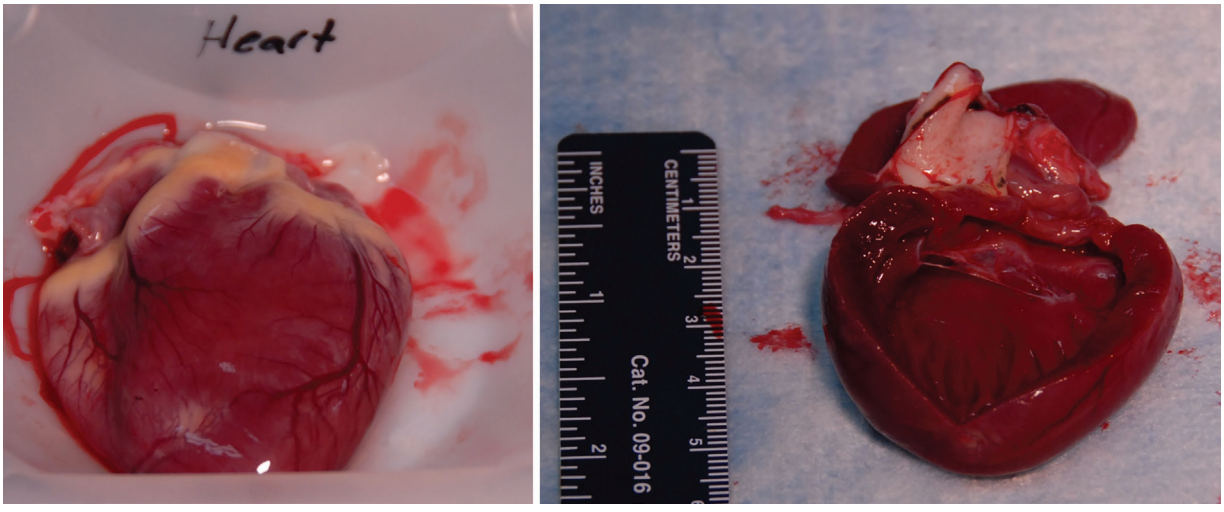

FIGURE 51.2 A flaccid heart from a cormorant (*Phalacrocorax* spp.), dermally exposed with <15% coverage of weathered MC252 crude oil over a 3-week time period. On the *left*, note the rounded shape of the whole heart that is softer rather than firm to the touch. On cut section on the *right*, thinner walls of the ventricle can be appreciated.

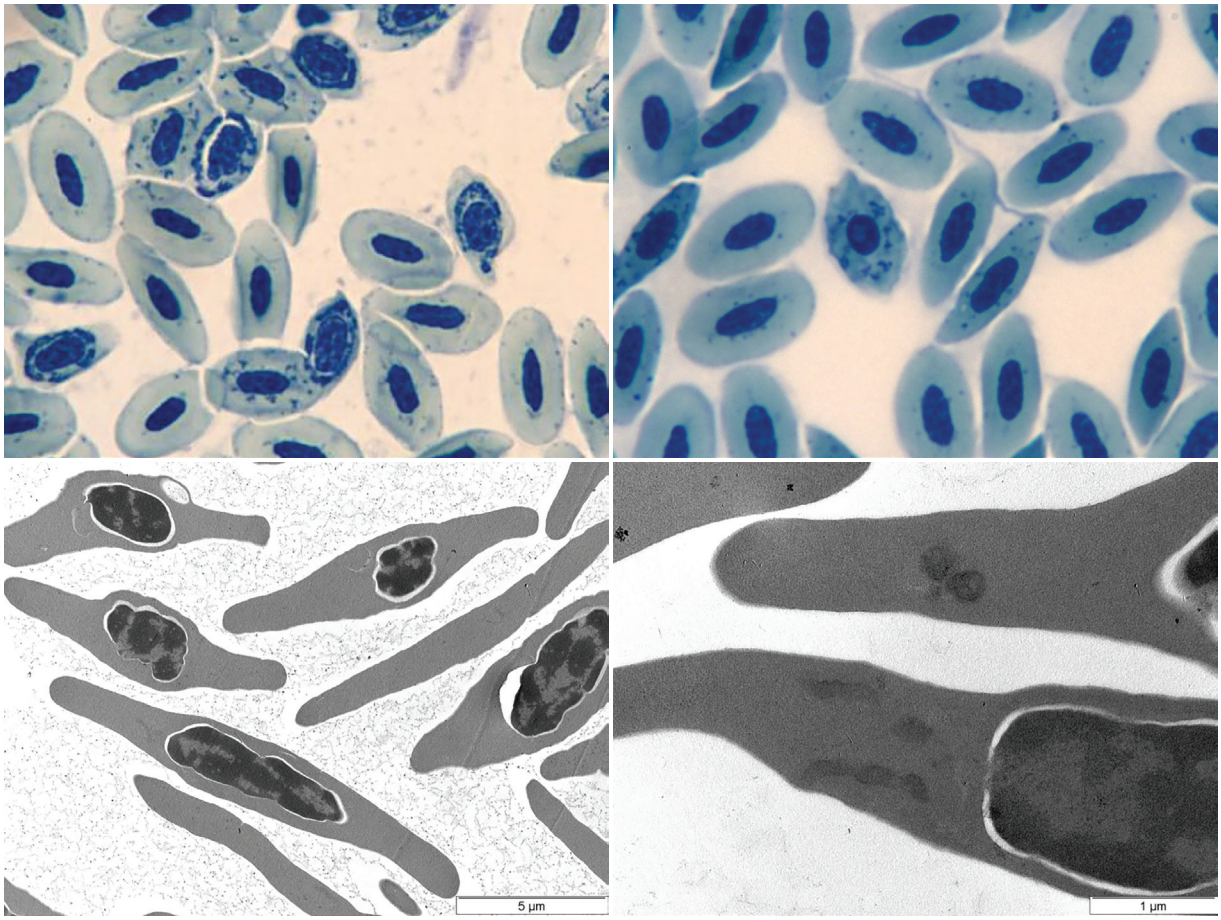

FIGURE 51.3 Reticulocytes versus Heinz bodies. The *top* images compare reticulocytes *(upper left)*, which are often found with dark blue reticulin ringing the nucleus in highly regenerative red blood cell (RBC) populations and an RBC with oxidant damage. The central crenated cell *(upper right)* has some reticulin, but fainter blue, round inclusions in the cytoplasm are consistent with Heinz bodies or denatured organelles. Light microscopy using new methylene blue stain at 1000×. Transmission electron micrograph of a normal-appearing RBC *(lower left)* from a control laughing gull exhibiting a homogeneous, gray cytoplasm with clumped chromatin in the nucleus. The white separation at the nuclear membrane and gray stippling in the background is processing artifact. A slightly higher magnification of electron-dense, darker cytoplasmic inclusions *(lower right)* found in >30% of RBCs of exposed birds only on transmission electron microscopy (TEM).

decreased oxygen-carrying capacity. While rapid acute hemolysis can cause lethal tissue hypoxia, even mild decreases in oxygen-carrying capacity impair organ function and can potentially reduce the ability of birds to fly, evade predators, and survive.[9]

Coagulopathy, suspected based on reduced blood clotting in cormorants both orally and dermally exposed to oil, was confirmed by determining activated clotting times in double-crested cormorants and pigeons that were dosed with artificially weathered MC252 crude oil. Coagulopathy results in blood loss through the GI tract (hematochezia) and other vascular leakage, which can directly cause anemia.[33,47] Often with extravascular hemorrhage (Figure 51.4), protein values will decrease.

Stress Response

Petroleum oil ingestion is reported to cause direct insult to the adrenal cortex.[9] It is hypothesized that the adrenal gland is particularly vulnerable to disruption due to its high vascularity and P450 enzyme concentrations.[48] Oiling directly and indirectly affects pituitary corticosteroid release. The immediate stress of oiling, capture, and washing likely increases endogenous corticosteroid release, leading to reduced immunocompetence and increased catabolism. After several weeks of exposure to sublethal doses of crude oil, experimental house sparrows *(Passer domesticus)* had less circulating corticosterone and cortisol.[48]

Immunologic Effects

Oil exposure increases inflammatory response in birds due to direct irritation but also causes immunosuppression from corticosteroid release.[9] Lymphopenia has been reported in oiled herring gulls and mallard ducks.[1] Cormorants in both experimental and control groups had decreases in heterophil and lymphocyte counts, suggesting that glucocorticoid release during captivity was a factor.[49] Cormorants administered approximately 8 mg/kg weathered MC252 oil had fewer

FIGURE 51.4 Coagulopathy in MC252 weathered crude oil–exposed birds was suspected at gross necropsy due to significant quantities of whole blood with no clots in the coelomic cavities.

inflammatory lesions on necropsy compared to control or low-dose birds, suggesting immunocompromise that could be the result of bone marrow suppression (see also *Current Therapy in Avian Medicine and Surgery*, Vol 1, Chapter 11, Immunology).[44]

Hepatic Effects

PAHs are metabolized by cytochrome P450 enzymes (phase 1) to produce reactive epoxides, which cause oxidative stress.[9] Specifically, CYP1A enzyme activity, which is a biomarker for PAH exposure in birds and other animals, is upregulated by aryl hydrocarbon receptors (AhR).[50,11] CYP1A induction was increased 24-fold in cormorants dosed orally with artificially aged MC252 petroleum compared to control birds.[51] Other evidence of oxidative damage in experimentally dosed cormorants and laughing gulls included a linear dose-dependent increase in total hepatic glutathione concentrations.[45,51] Cormorants also had a dose-dependent linear decrease in hepatic superoxide dismutase and glutathione peroxidase activity.[51]

Hepatic failure in oil-exposed cormorants was evidenced by decreased plasma cholesterol, albumin, uric acid, and total protein plasma concentrations.[49] Hypoglycemia was present while alkaline phosphatase (ALP), alanine transaminase (ALT), aspartate aminotransferase (AST), γ-glutamyl transferase (GGT) activities, and bile acids concentration all increased in orally dosed birds; hypoglycemia and increased ALT activity also occurred in dermally exposed birds.[49] Livers from experimentally dosed laughing gulls, cormorants, and western sandpipers were grossly enlarged with increased normalized weights, but histologic lesions were not evident, suggesting that the change was due to upregulation of microsomal enzymes, edema, or undetected causes.[33,44,45] Hemosiderosis has been reported in oiled birds, but despite evidence of hemolysis and anemia, there was minimal evidence of hemosiderosis in experimental gulls and cormorants.[44,45] This finding is consistent with anemia due to hematochezia (blood loss in the GI tract).

Renal Effects

Increased plasma urea, uric acid, and phosphorus concentrations in cormorants exposed to oil dermally or orally indicated renal insufficiency.[49] Renomegaly, documented by normalized weights, was found in experimentally oil-exposed cormorants and laughing gulls in comparison to control birds.[44,45] Histologic renal lesions included renal tubular epithelial cell hypertrophy, lymphoplasmacytic interstitial nephritis, and multifocal mineralization.[44]

Musculoskeletal Effects

Muscle damage could be due to direct oxidative damage, excessive preening, or injury, and was evident in exposed cormorants as elevated plasma creatine kinase (CK) and AST activities.[49] Experimentally dosed laughing gulls had elevated plasma 3-methyl histidine, a marker of muscle wasting.[45] Oil-exposed homing pigeons had evidence of increased CK and AST activity indicating myocyte damage that worsened with the distance flown. These birds were only oiled on wing and tail tips, with controls similarly handled but painted with water instead of oil. Control birds did not exhibit CK or AST activity above the reference interval for the population. It is hypothesized that the muscular injury in the oil-exposed birds was indirect due to exertional myopathy resulting from oil-damaged flight feathers (K. Harr, personal communication, 2021).

Thyroid Effects

Thyroid function is essential for growth, reproduction, neurodevelopment, immune function, and metabolism.[52] A study of tree swallow *(Tachycineta bicolor)* nestlings in areas of oil sand mining found that thyroid activity was altered with exposure to sulfur dioxide, naphthalene, and fluorene compounds, affecting response to cold temperatures, growth, and survival outcomes.[52] Experimental cormorants with dermal exposure to artificially weathered DWH oil had thyroid follicular hyperplasia on histology.[44] Possible causes of thyroid gland upregulation include direct effects of oil exposure and, indirectly, feather damage as the thyroid is important both for increased metabolic rate in thermoregulation and for feather production.[44]

TREATMENT OF OILED BIRDS

Birds with >10% surface oiling are unlikely to survive without intervention.[40,53,54] Species vulnerability and expected response to treatment are important when making treatment decisions for oiled birds.[55] Survival rates for rehabilitated birds vary with species, type of oil, speed of response, and rehabilitation methods but can reach 98% in larger birds and penguins. Unfortunately, oil exposure and stress of captivity can cause mass mortality in other species, including common loons *(Gavia immer)* and murres. Return of rehabilitated birds to the reproductive population is variably reported.[42,43] Studies in little blue penguins, California brown pelicans *(Pelecanus occidentalis californicus)*, and other species have found decreased breeding success, and one study found reduced hatchability of eggs laid by oiled and rehabilitated penguins compared to control birds during the first breeding season after release.[41–43,56] Further viability studies to determine offspring fledge success rates are needed to assess the value of rehabilitation of oiled birds.[57] Release of birds likely to have

poor reproductive success into the ecosystem is expected to be detrimental to the overall population.

As with any other toxin exposure, general management includes stabilizing the patient, decontamination, and symptomatic and supportive care. Stabilization of oiled murres prior to washing took up to 9 days.[35] Mindful of minimizing stress in oiled birds, stabilization can include maintaining normal body temperature for the species, maintaining hydration and electrolyte balance using appropriate fluid therapy, and supplemental feeding to improve body condition in birds that have experienced weight loss.[58] Currently recognized best practices for cleaning oiled birds require successive washes with a solution of 1% to 2% Dawn dishwashing detergent (Procter and Gamble Corporation, Cincinnati, OH) and warm water (41°C, 105.8°F), followed by repeated rinsing to remove all oil and detergent residues to allow restoration of normal properties of feathers.[41,42,59] Cleaned birds should be given access to pools of clean water and time to allow proper preening and swimming behavior and restoration of the insulating and water-resistant properties of feathers, which can take anywhere from 2 to 129 days depending on the species.[35,42,43,59] It is important to consider the natural history of the species, pelagic versus freshwater, during this period. A study on rehabilitation of pelagic birds found that murres and northern fulmars *(Fulmarus glacialis)* housed with freshwater pools had declines in serum sodium and chloride concentrations, which could affect their survival.[58]

Experimental studies in murres found that structural changes to feathers caused by oiling did not improve significantly over 48 hours, and, therefore, improvement was considered unlikely without human intervention.[20] Interestingly, another study of murres affected by an oil spill off the coast of California determined that more heavily oiled birds were likely to have higher body masses and packed cell volumes than lightly oiled birds and therefore were more likely to survive to release.[35] The authors hypothesized that heavily oiled birds came to shore more quickly and were collected soon after oiling, reducing exhaustion and catabolism. Most of the murres that died during rehabilitation died soon after bathing or within 48 hours after arrival at the rehabilitation center.[35]

A study of western sandpipers found that lightly and moderately oiled birds with access to clean freshwater were able to recover from feather damage within 2 and 10 weeks, respectively.[30] A study of African penguins *(Spheniscus demersus)* found that 93% of oiled birds entering rehabilitation survived to release.[60] This success was, in part, attributed to their relative lack of stress around humans.[60] Factors that were found to decrease survival in oiled murres included low body weight (below 675 g, or 66% of the mean weight for wild murres), packed cell volumes $< 15\%$, total plasma protein < 0.8 g/dL, and body temperature < 36.1°C.[35,42,43,61]

SUMMARY

Crude oil is a complex mixture of hydrocarbons, which can be fractionated into different components with different properties. The composition of crude oil varies between different geographic sources and over time due to weathering. Therefore it can be expected that these complex cocktails of hydrocarbons, heavy metals, and aromatic compounds have a wide variety of toxic effects including, but not limited to, hypothermia, inhibition of flight and buoyancy, intestinal malabsorption, endocrine and immunologic disruptions, blood dyscrasias, cardiac damage, and multiple organ system damage. Addition of Corexit 9500, which has a significant component of volatile aromatic hydrocarbons, results in increased bioavailability of some toxic petroleum components and can result in increased biotoxicity. Studies on rehabilitated oiled birds have had variable results for survival and future reproductive competence, but the number of studies are few and often incomplete as no controls have been included. Hence, further studies are needed to properly evaluate long-term effects and prevent rehabilitation and release of nonreproductive birds into an already stressed ecosystem.

CHAPTER 52

Anthropogenic Toxins

Jesse A. Fallon

INTRODUCTION

Humans have altered landscapes in remarkable ways that have improved our ability to survive and thrive as a species. Unfortunately, as we modify the world to our interests, we inevitably pollute the environment we rely on, and the consequences of these pollutants to wildlife continue to increase in parallel with our ever-expanding population. While, at times, anthropogenic pollutants can have obvious acute impacts on individuals and populations of wildlife (e.g., large-scale oil spills), more often the effects are more subtle and time-delayed. The effects of anthropogenic toxins on wildlife must certainly be evaluated at the level of individual animals, but ultimately it is more important to consider the effects at the level of populations, communities, ecosystems, and biospheres. Avian veterinarians, at the interface of human-animal-environmental health, must therefore consider the well-being of these broader communities in addition to their individual patients. Evaluating this bird's-eye view of anthropogenic toxins allows us to determine the most efficient and effective actions to prevent or remediate detrimental effects.

When approaching ecotoxicology, it is important to realize that toxicity testing under realistic environmental conditions is much more complex than testing the effects of a single chemical on a single species. The relationship of a particular toxin with a particular target species is complex and is influenced by various known and unknown environmental factors, seasonality, species and sex differences, as well as interactions with other compounds. Despite this complexity, there are numerous compounds and elements that have undeniable adverse effects. This chapter provides a summary of some well-studied anthropogenic toxins and their effects on wild birds. Rather than intending to provide clinicians with specific treatment guidelines for environmental toxin exposure, it provides an overview of the ecological consequences of anthropogenic toxins in the environment.[1] This ecotoxicological approach has importance for regulatory agencies, energy producers, agricultural industries, and individual consumers to help reduce the detrimental impact that our way of life has on wild bird populations. For further information on the treatment of intoxications, the reader is referred to *Current Therapy in Avian Medicine and Surgery*, Vol 1, Chapter 18, Advancements in Diagnosis and Management of Toxicologic Problems.

PESTICIDES

Pesticides are a group of chemicals used for the destruction of fungi (fungicides), bacteria (bactericides), weeds (herbicides), insects (insecticides), and rodents (rodenticides). These compounds are used on both residential and industrial scales around the world and are intended to target the physiology and survival of pest species. However, they can also have unintended consequences on nontarget species, including birds. Of these compounds, insecticides and rodenticides are the greatest risk to individuals and populations of wild birds.

It is important to realize that there is no centralized database that collects the information on avian mortality attributed to pesticides. These incidents can be difficult to detect, monitoring efforts are generally lacking, and relatively few carcasses are likely to be recovered. Furthermore, the sublethal, more protracted effects such as reduced fecundity, disturbance of behaviors, reduced prey availability, changes in migration patterns, and unrecognized effects of pesticides are rarely fully elucidated.

INSECTICIDES

Insecticides have been used for centuries to increase the productivity of crops and reduce the population of arthropod vectors of diseases that affect humans and domestic animals. However, there are numerous examples of damage to nontarget species, especially birds. These unintended consequences can be particularly problematic in part because of the staggering volume of pesticides produced and applied around the world, with the United States, European Union, China, and Brazil being the largest producers. Each year in the United States alone, 1 billion pounds (453,592,370 kg) of pesticides are used, while worldwide estimates suggest an annual use of approximately 5.6 billion pounds (2,540,117,272 kg).[2,3]

Insecticides are commonly grouped by their chemical makeup and the functional class of the active ingredient. Although there are thousands of compounds used as insecticides, those of greatest concern to bird populations include organophosphates, carbamates, and organochlorines (Table 52.1). There are hundreds of individual compounds that fall into one of these three categories.

One of the most well-known anthropogenic toxins to have a dramatic impact on bird populations was the organochlorine

TABLE 52.1
Classification of Insecticides With High Risk to Wild Bird Populations

Chemical Group	Mechanism of Action	Examples of Specific Chemicals
Organochlorines	Hyperexcitation of nerves by altering function of sodium channels and disturbing gamma-aminobutyric acid (GABA) neurotransmission	Dichlorodiphenyltrichloroethane (DDT), methoxychlor, dieldrin, chlordane, toxaphene, mirex, kepone, lindane, and benzene hexachloride
Organophosphates	Hyperstimulation of nicotinic and muscarinic receptors through inhibition of acetylcholinesterase	Monocrotophos, chlorpyrifos, dimefox, parathion, fenitrothion, fenthion, coumaphos, dichlorvos, demetox, malathion, trichlorfon
Carbamates	Hyperstimulation of nicotinic and muscarinic receptors through inhibition of acetylcholinesterase	Carbofuran, carbaryl, dimethane, pyrolan, aminocarb, aldicarb, vernolate, pebulate, butylate, methane, ferban, amoban, naban, zineb

pesticide dichlorodiphenyltrichloroethane (DDT). Organochlorines, which exert their effect via hyperexcitation of nerves by altering the function of sodium channels or by disturbing gamma-aminobutyric acid (GABA) neurotransmission, are highly lipid soluble and resistant to degradation, making this class very persistent in the environment with rapid bioaccumulation.[4] DDT was used extensively in North America during the 1940s, 1950s, and 1960s, both as an agricultural and household pesticide. The insecticide caused direct mortality in many birds. However, the more insidious effect of the compound was to reduce the transport of calcium from the bloodstream into developing eggshells, leading to eggshell thinning. The combination of widespread use, rapid bioaccumulation, and mechanism of action caused drastic declines in populations of brown pelican *(Pelecanus occidentalis)*, osprey *(Pandion haliaetus)*, peregrine falcon *(Falco peregrinus)*, and bald eagles (*Haliaeetus leucocephalus*; Figure 52.1).

The documented negative environmental effects of DDT led to most developed countries banning its agricultural use in the 1970s and 1980s, and the 2004 Stockholm Convention on Persistent Organic Pollutants put a global restriction of its use to vector control only. Despite these restrictions, DDT continues to be used for agricultural purposes in India and North Korea, and it is used for vector control in many countries in Asia, South America, and Africa to reduce the risk of vector-borne diseases such as malaria and leishmaniasis, in humans.[5] Therefore DDT still poses a risk to wild birds residing in or migrating to these countries, making hemisphere-wide conservation initiatives an important component of wildlife monitoring and management. Furthermore, because of the persistence of DDT and its breakdown products (dichlorodiphenyldichloroethylene [DDE] and dichlorodiphenyldichloroethane [DDD]), which have similar chemical and physical properties in soils and biota, the risk of exposure persists for many decades. Finally, while the use of DDT was restricted, this did not extend to all organochlorine pesticides. For example, compounds such as the miticide dicofol are still available for general use around the world; hence, their detrimental effects continue to be a concern.

FIGURE 52.1 The organochlorine pesticide dichlorodiphenyltrichloroethane (DDT), used extensively in North America during the mid-20th century, lead to declines in populations of predatory birds including the bald eagle *(Haliaeetus leucocephalus)*. (Photo courtesy Derek Courtney.)

As restrictions became more stringent on organochlorines, organophosphate and carbamate insecticides became much more commonly used. Both chemical types inhibit acetylcholinesterase, which results in hyperstimulation of nicotinic and muscarinic receptors, leading to both parasympathetic and sympathetic stimulation of the autonomic nervous system as well as central nervous system abnormalities in individuals exposed to toxic doses. Because insects and vertebrates have similar mechanisms of nerve transmission, toxicity can have lethal effects in target insects, as well as in fish, reptiles, amphibians, mammals, and birds. Birds are more sensitive to acute exposure to anticholinesterase pesticides than mammals due to more rapid binding and reduced detoxifying enzymes.[6,7]

Organophosphates are a readily available class of insecticides used extensively for agriculture, mosquito control, and residential purposes. Like organochlorines, these compounds can be toxic to vertebrates and, to a lesser extent, can bioaccumulate.[8] There are many well-documented reports of direct mortality in birds exposed to these compounds. For example, since its introduction in 1964, the organophosphate monocrotophos has directly been linked to more than 100,000 bird deaths, either through ingestion of seeds sprayed or ingestion of insects coated with the compound. Some of these mortality events can be dramatic, including the confirmed direct mortality of 5,000 Swainson's hawk *(Buteo swainsoni)* in Argentina over the course of one farming season.[9]

Some organophosphates, including monocrotophos, have been recently banned in many countries including the United States, European Union, and China. However, there are dozens of organophosphates still in heavy use, even in countries with restrictions, and some of the most dangerous are still being used around the world and continue to cause mortality in birds. Organophosphates were confirmed by the United States National Wildlife Health Center to be the cause of 335 separate mortality events, killing more than 9,000 birds in the country between 1980 and 2000.[10]

Carbamates are very similar in mechanism to organophosphates and have also been documented to cause mortality in many different species of birds. The most well-known example is carbofuran, which was estimated by the United States Environmental Protection Agency (EPA) to kill between 1 and 2 million birds annually prior to restricting the use of the granular formulation in 1994. Similarly, more than 5,000 ducks and geese were killed in five separate incidents when carbofuran was applied to alfalfa fields.[11] Sublethal effects, including reduced egg production, thinning of eggshells, and behavioral abnormalities, are triggered through exposure to carbamates, although these effects are difficult to link to pesticide exposure and quantify in wild populations.[11]

The consequences of organochlorines, organophosphates, and carbamates to individual and populations of birds cannot be understated. Fortunately, regulations have helped to ease the burden in recent years, but the use and misuse of these and other insecticides (e.g., neonicotinoids) must continually be monitored. As populations of many bird species continue to decline, we must do all we can to limit the use of these compounds whenever possible.

RODENTICIDES

Like insecticides, there are numerous compounds that are used as rodenticides. However, the most commonly used products, and therefore the greatest potential threat to wild birds, contain either anticoagulants, metal phosphides, mitochondrial toxins, or strychnine (Table 52.2). None of these compounds are species specific, and all of them have been documented to cause nontarget species toxicosis and death.

Anticoagulant rodenticides inhibit the enzyme vitamin K epoxide reductase and thus the synthesis of vitamin K, a crucial component in a number of normal clotting factors. Exposure to these compounds results in spontaneous bleeding throughout the body, leading to anemia and hypovolemia. These rodenticides are commonly categorized into first generation (e.g., warfarin), which typically require multiple exposure episodes to cause toxicosis, and second generation (e.g., brodifacoum), which are designed to cause toxicosis after a single exposure event. Of all the rodenticides, second-generation anticoagulants currently pose the greatest threat to individual birds and populations.

There are several factors that make second-generation anticoagulant rodenticides a threat to wild birds. First, they cause mortality from primary ingestion at very low doses. Second, they have historically been readily available to the general public around the world. Finally, and most importantly, they bear a high risk of secondary toxicosis (also called relay toxicosis) because of their persistence in tissues, which leads to bioaccumulation and biomagnification. Raptors, in particular, are at risk for exposure to these compounds because of their diet, and some species (e.g., owls) appear to have limited capability to metabolize these anticoagulants.[12] This results in longer elimination times compared to mammals and other birds, hence limiting their capacity for detoxification and increasing the risk for detrimental effects.

There are many reports of mortality in raptors exposed to second-generation anticoagulants, and numerous studies show widespread sublethal effects, with some demonstrating nearly ubiquitous exposure in certain regions.[13] Through opportunistic sampling of raptors, a high incidence of exposure to these rodenticides has been demonstrated in North America, Europe, Africa, Australia, and Asia. Because of the high risk of secondary toxicosis of second-generation anticoagulants, some countries, including the United States, have recently limited the availability of these compounds for use only by professional exterminators. Hopefully, this will reduce the risk of exposure of birds of prey to compounds like brodifacoum. However, an unintended consequence of these regulations is likely to be a higher incidence of exposure to other rodenticides such as zinc oxide, cholecalciferol, and bromethalin, as these products remain readily available to the general public.

The rodenticide bromethalin is a neurotoxin intended as a single-dose product. This chemical, a strong uncoupler of oxidative phosphorylation, results in nerve demyelination, spinal and cerebral edema, increased intracranial pressure, and ultimately neurologic dysfunction and death. Compared to

TABLE 52.2

Classification of Rodenticides With Risk to Wild Bird Populations

Chemical Group	Mechanism of Action	Examples of Specific Chemicals
Anticoagulants	Inhibition of the enzyme vitamin K epoxide reductase leading to spontaneous bleeding	First generation: chlorophacinone, diphacinone and warfarin Second generation: brodifacoum, bromadiolone, difenacoum, and difethialone
Bromethalin	Uncoupler of oxidative phosphorylation and neurotoxin resulting in nerve demyelination, spinal and cerebral edema, causing neurologic dysfunction	Bromethalin
Metal phosphides	Generates phosphine gas in the acidic environment of the stomach resulting in respiratory damage	Zinc phosphide
Strychnine	Inhibits the neurotransmitter glycine resulting in rigidity, seizures, and neurologic damage	Strychnine

anticoagulant rodenticide toxicosis, bromethalin toxicosis is difficult to recognize both ante- and postmortem, as the primary signs can mimic other neurotoxins (e.g., lead), infectious encephalitis (e.g., West Nile virus), or trauma. Although bromethalin toxicosis is commonly reported in domestic dogs and cats from primary exposure, there is very little data on the risk of bromethalin to wild birds, although the LD_{50} of bromethalin in birds is likely similar to that of mice.[14] Additionally, there is recent evidence of bromethalin toxicosis in free-ranging conures in an urban setting, although the source of bromethalin in these cases was not determined.[15] To date, secondary toxicosis from the ingestion of prey has not been proven. Although it is believed that this compound does not pose a high risk of relay toxicosis, there is a paucity of data on the effect of bromethalin in birds that feed on target rodent species. As increased restrictions on the use of second-generation anticoagulants come into effect, this compound will continue to become more commonly used (Figure 52.2). For these reasons, more research is needed to determine the risk of bromethalin on wildlife.

Zinc phosphide serves as rodenticide by virtue of its transition to highly toxic phosphine gas once the bait has encountered the acidic environment of the stomach. This gas causes severe irritation to the lungs and air sacs, which results in respiratory distress and death. Primary ingestion of zinc phosphide rather than secondary toxicosis is the highest risk to birds, with numerous studies indicating lethal effects to Anseriformes, Icteridae, and Galliformes allowed access to zinc phosphide pellets in experimental settings or were naturally exposed to the compound. Secondary exposure to zinc phosphide has been demonstrated to produce sublethal effects in great horned owls *(Bubo virginianus)* and bald eagles, although the risk of relay toxicosis leading to death appears to be low.[16,17]

FIGURE 52.2 Rodenticides are readily available to consumers throughout the world. In many countries, bromethalin has recently become more accessible than second-generation anticoagulant rodenticides in an attempt to reduce the risk of relay toxicosis in wildlife.

Strychnine is an indole alkaloid that, when ingested, inhibits the neurotransmitter glycine, resulting in rigidity, seizures, anoxia, and death. There are numerous reports of mortality events in dozens of bird species. Because strychnine is used around the world to target large scavenging mammal species such as coyotes and feral dogs, scavenging raptors are at particular risk. In Africa, large-scale, nontarget poisoning of vultures (e.g., bearded vulture *[Gypaetus barbatus]*, hooded vulture *[Necrosyrtes monachus]*, Cape vulture *[Gyps coprotheres]*, white-backed vulture *[G. africanus]*, lappet-faced or Nubian vulture *[Torgos tracheliotus]*, and white-headed vulture *[Trigonoceps occipitalis]*) and eagles (e.g., tawny eagle *[Aquila rapax]* and bateleur *[Terathopius ecaudatus]*) has been reported.[18] With more than half of old world vultures listed as vulnerable, threatened, or endangered, such large-scale losses can have devastating effects on populations.

Although birds typically succumb to insecticide and rodenticide toxicosis as a result of unintentional exposure, they are sometimes the target species of malicious poisoning. Hundreds of cases of malicious poisoning of raptors with these compounds are reported each year around the world.[19–21] These are preventable events. Public education about the value of scavengers in ecosystems, regulations on the availability of these products, and enforcement of existing laws protecting wild birds are paramount to reducing the incidence of this intentional and inappropriate use of pesticides.

As with insecticides, rodenticides can have enormous impact on individuals and populations of birds. Reducing the risk includes selecting compounds with low risk of relay toxicosis, limiting the access to these compounds by the general public, and selective and judicious use of rodenticides whenever possible.

HEAVY METALS

Heavy metals, so named because of their high molecular weight, are well known environmental pollutants. Although these metals are found naturally arising from weathering of certain rocks and volcanic eruptions, anthropogenic sources such as mining, smelting, agricultural use of pesticides and fertilizers, and burning fossil fuels have dramatically increased the presence of these metals in the soil, water, and air. In particular, mercury, lead, cadmium, and arsenic have been identified as metals of greatest concern to wildlife. These compounds can undergo bioaccumulation and biomagnification, putting long-lived and high trophic species at highest risk.

In experimental settings, each of these elements has been demonstrated to individually cause physiologic insult in a variety of bird species. However, because many of these compounds often occur in elevated environmental concentrations as a result of the same anthropogenic activities, it is often difficult in field studies to determine which of the compounds has the greatest impact on individuals and populations of birds. The primary exceptions to this are lead, mercury, arsenic, and, to a lesser extent, cadmium.

Lead

Although it is a naturally occurring element in the environment, lead has no functional role in biological systems and is toxic at very low levels of exposure. In birds, acute lead toxicosis causes lethargy, gastrointestinal stasis, anorexia, vomiting, diarrhea, anemia, disturbances of cellular metabolic functions, and neurologic injury leading to blindness, seizures, weakness, and death.[22–25] Chronic, low-level exposure leads to sublethal effects such as neurological damage, tissue and organ damage, and reproductive impairment.[26]

Lead has been used for centuries by humans for a variety of purposes, including plumbing, batteries, weights, solders, fusible alloys, radiation shielding, paint, and leaded gasoline. Fortunately, in many countries, lead has been banned for use in water pipes, paint, and gasoline, reducing the human risk of lead intoxication. However, despite the plethora of literature that identifies lead as a potent toxin to all vertebrates, it is still used extensively for hunting ammunition and fishing tackle throughout the world. Exposure to these sources of lead has been a known hazard to water birds (e.g., ducks, swans, and loons) for decades.[27] Upland game birds (e.g., doves and quail) and scavengers (e.g., condors and eagles) are exposed to lead from spent ammunition, with population-level consequences identified in some species.[28–31] Scavenging raptors are at particular risk, with up to 25% of bald eagles admitted to rehabilitation facilities carrying elevated lead concentrations.[32] The federally endangered California condor (*Gymnogyps californianus*; Figure 52.3) population continues to be at great risk in large part due to exposure to lead from spent ammunition found in offal piles and carcasses of shot game and pest species (see also *Current Therapy in Avian Medicine and Therapy*, Vol 1, Chapter 23, Conservation of Avian Species).[27,33]

Current data for raptors and avian scavengers demonstrate clear positive correlations of lead exposure during hunting seasons.[34] The hazard of ingested lead sinkers and fishing tackle is well documented in swans (*Cygnus* spp.) and loons (*Gavia* spp.), and restrictions on the sale or use of lead weights have been instituted in parts of the UK, Canada, the United States, and other countries in order to reduce the impact on these and other vulnerable species. Fortunately, these regulations on recreational hunting and fishing have been shown to reduce the risk of lead toxicosis, with particularly dramatic effect on waterfowl in North America and the European Union, where rates of lead shot ingestion have been reported to be reduced by up to 50% to 64% in some populations.[35,36] However, the worldwide use of lead for hunting and fishing continues to have a significant impact on wild bird populations.

FIGURE 52.3 Lead intoxication is a common cause of mortality in critically endangered California condors *(Gymnogyps californianus)*. There are fewer than 300 California condors in the wild; scientists use numbered wing tags to identify individual birds. (© Courtesy Evan McWreath mcwreath@accawv.org)

Mercury

Inorganic mercury is a toxic, naturally occurring element that has been used in a variety of applications but enters the environment predominately through the burning of fossil fuels, particularly coal, causing mercury to become airborne. This airborne mercury can travel over a range of distances, from a few feet to thousands of miles, before it falls to the ground in rain, snow, or simply by gravity, ultimately entering the soil or aquatic ecosystems. Once in water or soil, mercury enters a complex cycle, which includes bioconversion by bacteria into more soluble forms including methylmercury. The conversion to methylmercury is important both because it is more toxic than inorganic mercury and because organisms require considerably longer to eliminate methylmercury. Bacteria that produce methylmercury are either consumed by the next higher level in the food chain or the bacteria may release the methylmercury into the water where it can quickly adsorb to plankton. Bioaccumulation through the food web continues through macroinvertebrates, to herbivorous fish, to piscivorous fish, and finally to fish-eating birds and mammals, leading to increasing concentrations of methylmercury through each trophic level.

There is a large body of research demonstrating both elevated concentrations of and negative effects from mercury in both fish-eating birds and some insect-eating songbirds.[37] The accumulation of mercury in free-ranging birds is rarely lethal, but songbirds and waterfowl with blood concentrations above 5 μg/g have demonstrated reduced reproductive output, compromised immune function, and avoidance of high-energy behaviors.[37] Reduced reproductive output in particular has been demonstrated to have significant impact on local populations. For example, in the Adirondack Mountains of New York state, common loons *(Gavia immer)* with elevated blood mercury concentrations had a 32% to 56% reduction in the number of chicks fledged per year.[38]

Arsenic

Arsenic, often classified as a heavy metal, is a metalloid, having properties of both a metal and a nonmetal. It occurs naturally in soil and in several types of rock, but anthropogenic sources

including mining-related activities, coal combustion, pesticides, and wood-preserving arsenicals greatly increase the regional environmental burden.[20] Arsenic causes toxicosis primarily by inducing oxidative stress through reduction in the activity of antioxidant enzymes and production of reactive oxygen species, leading to damage to cells, tissues, and genotoxicosis.[39] The effects on birds are typically sublethal and include reduced food intake, weight loss, growth retardation of chicks, reduced reproductive success, and hepatic dysfunction.[40] Because elevated arsenic concentrations in blood and tissues occur in conjunction with elevations in other heavy metals as a direct result of the same anthropogenic sources, identifying arsenic as the definitive cause of physiologic injury in field studies is often impossible. Experimental studies, however, have shown that arsenic exposure reduces growth rates and survival in wild birds.[41]

Cadmium

Cadmium is a known carcinogen, mutagen, and teratogen that has been demonstrated to cause severe deleterious effects on freshwater invertebrates and fish. However, the effect of environmental exposure to birds is less clear, with relatively little data available compared to body of research on lead and mercury. Anthropogenic sources of cadmium include smelter fumes, burning of fossil fuels, fertilizers, and municipal wastewater, with the highest concentrations in localized regions of smelters or urban industrialized areas. Experimental studies in captive birds have demonstrated growth retardation, anemia, kidney insult, and testicular damage; however, these effects were observed at higher concentrations than in aquatic biota. Elevated cadmium concentrations have been found in the kidneys of a number of species ranging from raptors to songbirds. Additionally, renal tubule damage has been correlated to elevated cadmium concentrations in wild pelagic seabirds (e.g., Manx shearwaters *[Puffinus puffinus]*, fulmars *[Fulmarus glacialis]*, and puffins *[Fratercula arctica]*) and white-tailed ptarmigan *(Lagopus leucura)*.[42,43] Further research is needed to evaluate the population-level effects of cadmium.

Except for lead, reducing the burden of elevated heavy metal concentrations in the environment depends on decreasing human reliance on fossil fuels and careful use of fertilizers. These changes can occur at the local, regional, national, and international levels through regulation, environmentally conscious energy companies, and public demand. Individuals can reduce their contribution to heavy metal contamination by walking, biking, or taking public transportation to work or telecommuting, choosing reusable items rather than disposable, and by conserving energy in their homes and workplaces.

SUPERFUND SITES

Although anthropogenic toxins are often distributed in relatively small quantities across large regions, there are numerous examples of massive contamination in very consolidated locations. In the United States, these localized areas with massive contamination requiring a long-term response to clean up hazardous materials are often referred to as Superfund sites. The designation of Superfund sites began following the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, which authorizes

FIGURE 52.4 Environmental Protection Agency (EPA) Superfund Signage at the Clearview Landfill with covered landfill in background. There are more than 1,300 locations in the United States identified by the EPA as Superfund sites. These sites have soil and water that are heavily contaminated with volatile organic compounds, polychlorinated biphenyls, polyaromatic hydrocarbons, and heavy metals. (Photo taken January 2021, by Dwkaminski, Wikimedia Commons.)

the EPA to identify the most contaminated sites posing a threat to public and environmental health and to outline a strategy for remediation (EPA 2020). There are at least 40,000 Superfund sites distributed throughout the United States, with more than 1000 identified as severe enough to be eligible for aggressive EPA remediation efforts (Figure 52.4). Many other countries have similar programs, as localized, heavily contaminated sites are present around the world.

Superfund sites arise from a variety of sources including mines (e.g., copper, asbestos, uranium), smelters (e.g., lead), weapons manufacturing and testing facilities, waste from chemical companies, water, and soil nearby a variety of industrial and agricultural sources, and landfills where hazardous chemicals and waste were deliberately and inappropriately dumped (Figure 52.5). The list of contaminants found at these sites is long and includes metals such as lead, mercury, zinc, and arsenic, pesticides such as DDE and DDT, volatile organic compounds (e.g., benzene), polycyclic aromatic hydrocarbons (PAH), polychlorinated biphenyls (PCBs), and radioactive compounds (e.g., uranium 234, 235).

Myriad negative effects on birds and other wildlife have been documented near these heavily contaminated sites. Specifically, elevated concentrations of contaminants in wild birds near these sites have been correlated with organ dysfunction, endocrine disruption with gonadal disturbance and skewed male-female ratios, population age-structure aberrations, reduced growth rate, poor fledgling success, and reduced adult survival in dozens of species from many different families of birds.[44]

Overall, there is a great deal of public support for remediation of these heavily contaminated sites. Once remediation of a site is initiated, it can take decades and millions of dollars to restore sites to "safe" environmental states. Whenever possible, responsible parties are forced to bear the cost of cleanup. However, in many cases, there is no clearly identifiable responsible

FIGURE 52.5 The "Valley of the Drums" in Bullitt County, KY, was an uncontrolled industrial waste dump that helped prompt the passage of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, which allocated federal funding for Superfund site cleanup. Heggenhougen HK: International encyclopedia of public health. In De Rosa CT, Fay M, Keith LS, et al., editors: *Hazardous wastes*, 2008, Academic Press, pp 107–121. https://doi.org/10.1016/B978-012373960-5.00279-3.

party, or the pollution was caused by bankrupt parties. In these cases, tax money is required to support expensive cleanup efforts, and the extent of remediation depends on the appropriation of funds to the EPA from the federal government for this specific purpose.

SUMMARY

Despite their effects on birds and other wildlife, anthropogenic toxins are present throughout the environment. In some cases, remediation of localized toxins can be successful in restoring the environment to conditions that are safe to birds. Most importantly, these toxins need to be recognized and regulated by individual countries, and international cooperation for the safe and judicious use of pesticides and waste chemicals is critical to the ongoing health of our planet.

There are straightforward strategies that we can employ to reduce the negative impact of our daily lives on ecosystems. Specifically, responsible natural resource extraction, processing, and transport, proper disposal of dangerous chemicals, and reduced use of chemical pesticides are achievable goals. Good stewardship of our environment benefits not only the birds and wildlife that we cherish, but also keeps this planet a healthier place for all plants and animals, including humans. Fortunately, there are several actions that individuals can take to help reduce the risk of anthropogenic toxins to birds:

1. Encourage legislative bodies to reduce the ongoing use and volume of anthropogenic toxins in the environment. This includes restrictions on the use of lead ammunition, reducing the availability and use of pesticides (particularly carbamates and organophosphates) and rodenticides, to targeted, critical applications, demanding responsible extraction, transport, and refinement of natural resources, and requiring remediation of Superfund sites. This must be approached at the local, national, and international levels.
2. Reduce our individual contribution to these environmental toxins by choosing less toxic ammunition and fishing tackle, judicious personal use of pesticides and rodenticides, purchasing products from environmentally conscious companies, and reducing our reliance on fossil fuels.
3. Educate friends, families, clients, students, and the general public on the risks of anthropogenic toxins and alternative choices that can help improve the health of ecosystems.

CHAPTER 53

Wildfires

Michelle G. Hawkins • *Jamie L. Peyton*

Visit eBooks.Health.Elsevier.com for a complete set of references.

INTRODUCTION

A wildfire or bushfire by definition is an uncontrolled fire. While wildfires historically occurred in wild, unpopulated areas, they can occur anywhere and can harm homes, agriculture, humans and the animals in their path, including birds. In recent years, wildfires in North America, Australia, and Europe have gotten progressively larger causing extensive damage to life and property. Whole towns have been reduced to ash as wildfires increase in size and intensity.

Regardless of country, disaster incident response management systems are vital to have in place to ensure an organized response when any disaster incident occurs, including wildfires. In the United States, for example, the Incident Command System (ICS) manages wildfire incidents of any size and provides procedures for controlling personnel, facilities, equipment, and communications for any type of incident (wildland fire, search and rescue, structural fire). It is intended to be staffed and operated by qualified personnel from emergency services agencies; ICS may involve personnel from a variety of agencies. The National Park Service and the US Department of Agriculture (USDA) Forest Service are often first responders to these incidents and along with battalion chiefs from the local or regional fire department may become the Unified Command for the incident.

Local and regional disaster groups may be activated to assist in sheltering and evacuation of animals during a wildfire and are commonly part of the Unified Command of the ICS. Veterinarians activated during a wildfire incident should be prepared to treat a wide range of patients, sedate/anesthetize different species in the field, treat various degrees of burns, bandage wounds, and fractures, provide antibiotics and other medications as needed (and within the guidelines of the Food Animal Residue Avoidance Database [FARAD] for food-producing animals or wildlife that may be utilized as food in the United States), and provide supportive care. Wildlife is generally transferred to a local wildlife rehabilitation facility and so veterinarians working in this capacity may be called upon to provide immediate care for injured and burned wildlife.[1]

Best practices for common injuries identified during a wildfire have been established for many species but to date these have not been developed for birds. Not only are companion psittacines and passerines rescued from fires but backyard poultry, waterfowl, and wildlife are nowadays also rescued from wildfires in meaningful numbers. Disaster groups are realizing that protocols for housing and medical care still need to be established for all bird groups to have a unified response.

Disasters can quickly overwhelm health care systems. A database for tracking identification and health of animals is a critical component of effective preparation, real-time communication during disasters, and retrospective analysis.[2] The database should provide information that supports additional efforts in the recruitment of volunteers with specific skill sets (e.g., avian veterinary specialists) and to adjust daily supplies needed. A disaster database is not intended to replace individual veterinary medical records but to provide an overarching view to assess the daily veterinary needs and supplies, to help manage volunteer deployment, and to establish an objective surveillance tool for evaluation.[2] The database had specific goals of assessing the types and numbers of animals affected by the disaster, recording the precise spectrum of illness and injuries, monitoring treatment and disposition, acquiring needed veterinary supplies, and facilitating future evaluation of the response.

In November of 2018, California experienced its most destructive wildfire in history, the "Camp Fire". The fire burned over 18 days and 150,000 acres and destroyed 18,804 structures in Butte County, CA.[2] The town of Paradise was the epicenter of the inferno. The fire raged through residential and rural neighborhoods and incinerated homes and entire communities. Four days after the fire began, it was classified as a major disaster by the federal government, the worst of 16 fire disasters declared by the Federal Emergency Management Agency (FEMA) in California in 2018 alone. Over 600 backyard chickens and waterfowl were rescued—a first in California.[2] Avian species were primarily treated for burns and dehydration; ectoparasites and lameness were also commonly documented.[2] Debriefing from this incident led to the awareness that development of best practices for housing and medical care for backyard poultry and waterfowl were especially necessary for fire disaster preparedness.[2] Birds are treated at their "shelter in place" facility as much as possible without moving them, so family members and disaster workers can find and identify the animals more easily. If the severity of wounds requires more aggressive therapy and continuity of care, the birds should be transferred to a disaster veterinary facility for further care.

Wildfires are predicted to continue in the western United States and in other parts of the world into the future.

Towns in Oregon and Washington states in the United States were also devastated by wildfires in 2019 to 2020,[3] and wildfires in Australia and Brazil in those years showed not only loss of life and home but also the direct effects on endangered species and other wildlife.[4] In northern California alone in 2020 a veterinary emergency response team evaluated 315 birds in the field while "sheltering in place" and another 630 birds were brought into shelters during evacuations and from search and rescue (M.G. Hawkins, personal communication, 2024). It is therefore important to be familiar with emergency housing, patient assessment, and treatment of burns and smoke inhalation in avian species.

EMERGENCY HOUSING

Not only are companion psittacines and passerines rescued from fires, but backyard poultry and waterfowl, falconry birds, ratites, and wild birds have also been rescued. Disaster groups are realizing that protocols for housing and medical care for these various species still need to be established to have a unified response. During the 2018 Campfire in California, almost 600 backyard companion birds were rescued in addition to their companion farm animal counterparts (Figure 53.1).[2] Debriefing from this incident has led to the development of best practices for housing, biosecurity, and medical care for backyard poultry and waterfowl by the state, but there is much more to be done to develop specific protocols for the many varied avian species that have already been presented to shelters.

PATIENT ASSESSMENT

With the paucity of literature to help guide veterinarians and animal caretakers, standards of care must be derived from the human literature. Avian patients on presentation should be evaluated like other trauma-based incidents with a full physical examination including assessment for shock, dehydration, and respiratory distress (see Chapter 34). Regardless of the presence of burn wounds, it is essential to treat the patient for life-threatening systemic conditions such as shock and dehydration prior to treatment of burn wounds (Figure 53.2).[5,6] In a recent publication evaluating the occurrence of comorbidities in burned wildlife, hypovolemia and dehydration were the most common problems noted on presentation.[1] This is comparable to what is typically noted in the human literature and associated with the secondary systemic inflammation from the burn wounds creating an increase in general capillary permeability.[7] In addition, animals are often not found until several days or weeks after their initial injury and access to water is not always readily available in evacuated zones. If hypovolemic shock is noted, these animals should be treated aggressively with isotonic intravenous (IV) fluid therapy until improvement of clinical signs. At a minimum, subcutaneous fluid therapy is recommended to provide additional volume and ensure adequate hydration support. When feasible, it is ideal to collect blood for a point-of-care blood gas and chemistry panel to assess initial signs of respiratory and renal compromise.

Cardiopulmonary evaluation is essential to monitor secondary injuries from smoke inhalation. Smoke inhalation injury has been characterized by thermal and chemical damage to the upper airway, lower airway, and pulmonary parenchyma, as well as systemic toxicity.[8] Over one-third of all human burn patients suffer from smoke inhalation injury, and mortality increases 20 times when this injury is present.[9] The exact occurrence in birds is unknown, but birds can exhibit marked tachypnea and dyspnea within a few hours of smoke exposure.[10] However, in recent fires in California, few birds exhibited overt clinical signs of respiratory distress even when severe burns were present. Diagnostics in human medicine include radiographs, bronchoscopy, and computed tomography (CT), but the main diagnosis is based on history of exposure and presence of clinical signs.[8,11] Blood gas markers such as carboxyhemoglobin and methemoglobin may more objectively help in identifying the severity of respiratory compromise.[12–14] Further studies are necessary to determine how these markers may be useful prognostically in detecting smoke inhalation injury in birds.

FIGURE 53.1 (A) During the 2018 Camp wildfire in California, almost 600 backyard birds along with livestock were rescued to a nearby fairground. Protocols for avian housing and biosecurity were not yet established. Initial housing for backyard chickens, turkeys, and waterfowl used dog carriers and species were not separated. (B) Small flocks were housed in livestock stalls, often next to pigs, creating additional biosecurity issues.

FIGURE 53.2 Regardless of the presence of burn wounds, it is essential to treat the patient for life-threatening systemic conditions such as shock and dehydration prior to treatment for burns.

THERAPEUTICS

There is currently no standard consensus on the treatment of smoke inhalation injury in human medicine and even less is known in avian medicine. A variety of therapies such as oxygen support and nebulization of bronchodilators, anticoagulants, antioxidants, and pain management are used in humans.[11,15,16] Beta-2 adrenergic agonists have been used to help decrease airway resistance, improve airway fluid clearance, decrease mucosal damage, and decrease inflammatory mediators within the airways (see also Chapter 28).[11,15] Nebulization of a mucolytic agent such as *N*-acetylcysteine (NAC) has also been evaluated and shown to be helpful in facilitating removal of excess secretions by breaking down disulfide bonds. NAC also has additional beneficial anti-inflammatory and antioxidant effects. The potential side effect of nebulization of NAC is bronchospasm, and therefore nebulization in conjunction with a beta-2 adrenergic agonist is recommended.[11,17,18] The use of nebulized heparin in human clinical trials has also shown improvement and may aid in the breakdown of fibrin binding in the airways.[9,19,20] At this time, none of these treatments have been assessed in avian species, so further evaluation is warranted. Oxygen supplementation with nebulization of saline and albuterol should at a minimum be considered. Despite its use for other respiratory conditions such as asthma, corticosteroid administration is not recommended for smoke inhalation injury.[16] It may be considered for treatment of initial airway edema but should always be used with caution in birds.[10,15] Human studies have shown no significant benefit; instead corticosteroids carry an increased risk for secondary lung infection.[8,16] This has also been noted in a case report on parrots with smoke inhalation that developed secondary aspergillosis after prolonged corticosteroid administration.[10] The use of diuretics has been described in the veterinary literature but has minimal supporting evidence and may exacerbate concurrent dehydration or hypovolemia.[10,21]

A pain management plan should always be developed early in the treatment period with the knowledge that the plan may change over the course of therapy (see also Chapter 35 and *Current Therapy in Avian Medicine and Surgery*, Vol 1, Chapter 20, Recognition, Assessment, and Management of Pain in Birds). Species variability occurs due to differences in pain sensitivity, the conscious response to pain, and the physiological response to analgesic therapy. Genetic variability with response to pain has been demonstrated at the individual level and in different strains of chickens.[22] Behavioral changes can be very subtle but are often the earliest signs of pain detected by animal care staff. Behavioral change does not manifest uniformly among the many different species of birds and observers must become familiar with the full range of normal behaviors for the species. Without knowing the range of normal behavior, an observer will find it extremely difficult to detect abnormal behavior, especially in prey species, which often only demonstrate cryptic and subtle changes. The outward behavior of a companion bird acclimated to handling does not accurately reflect the physiological changes occurring with stress-related hormones, respiratory rate, or body temperature.[23] Therefore it can be inferred that a bird in pain may also mask physiological changes associated with the pain. In lieu of species-specific pain scoring sheets for birds, there is tremendous value in using a generic pain scale of 1 to 10 to evaluate a bird's pain and the response to treatment and recovery from the painful condition. Effective analgesia is expected to show a marked, easily discernable change in posture or behaviors that will effect a reliable change in the subjective pain score. If no change in pain score occurs, then the drugs, dosage, or frequency of administration need to be reevaluated for that individual patient.

Significant differences in species-specific response to analgesics have been and are continuing to be identified in studies in birds (see also Chapter 35 and *Current Therapy in Avian Medicine and Surgery*, Vol 1, Chapter 20, Recognition, Assessment, and Management of Pain in Birds).[24] In addition, acceptable analgesics in food-producing birds are few and this can limit the ability of the veterinarian to administer certain pain medications. For example, in the United States there are no withdrawal times for opioid medications in food-producing birds, yet μ-opioid agonists appear to provide excellent analgesia for these patients. Often in disasters the owner of the animal is not known at the time of treatment, thus obtaining documented permission to treat the animal with the expectation of not eating the bird or its eggs in the future cannot be obtained. Withdrawal times for the use of meloxicam in laying chickens have been established and this medication is very useful for reducing inflammation as well as providing analgesia, but should also be used in moderation in the face of hypovolemia or dehydration.[25] Topical analgesics including prilocaine, lidocaine, and other compounded salves have also been found to be quite effective in reducing pain in humans; however, to our knowledge no studies have been published evaluating systemic uptake of these topical analgesics in any avian species.

A major component of smoke inhalation is also the risk of systemic toxicosis due to components of the smoke such as carbon monoxide (CO) and hydrogen cyanide (CN) toxicity (see also *Current Therapy in Avian Medicine and Surgery*, Vol 1, Chapter 18, Advancements in Diagnosis and Management of Toxicologic Problems). CO is released with the incomplete combustion of fossil fuels and biomass often seen in fire.[26]

Inhalation results in CO diffusion into erythrocytes where it binds to hemoglobin. CO directly competes with oxygen and has a 230 to 270 times greater affinity for hemoglobin, thereby displacing oxygen and resulting in carboxyhemoglobin and tissue hypoxemia.[26,27] Co-oximetry is a specialized blood gas analyzer that can detect concentrations of carboxyhemoglobin to evaluate severity[28] but it is not always widely available and standards have not been established for most avian species. Despite unknown percentages for clinical signs, sparrows were historically used after coal mine fires to detect elevated levels of CO due to their perceived increased sensitivity.[29] Increased levels of carboxyhemoglobin result in clinical signs ranging from tachypnea, nausea, neurologic abnormalities, and death.[26] The main treatment is administration of oxygen therapy to help increase oxygenation levels and facilitate displacement of the CO off the hemoglobin, and thereby decreasing its effective half-life.[30] In structural fires, CN is often a significant source of toxicosis resulting from the combustion of commercial products and incomplete combustion of natural fibers. Inhalation of cyanide results in cellular toxicity by CN binding to cytochrome oxidase within the mitochondria and halting oxidative production of ATP.[16,30,31] Clinical signs include tachypnea, dry red mucous membranes, altered mental status, seizures, and death. Definitive diagnosis for CN toxicosis can have a significant lag time due to the need for laboratory-specific assays. Treatment is often based on suspected exposure and clinical signs.[16,31] The main treatment is supportive oxygen therapy, but often antidote therapy is also required. The most commonly utilized antidote is hydroxycobalamin. This is a natural derivative of vitamin B_{12} and when administered can directly chelate CN to form cyanocobalamin (vitamin B_{12}), which can then be safely excreted renally.[16,32,33]

Due to the chaos and stress of evacuation during wildfires, patients should also be evaluated for any other traumatic injuries such as fractures, lacerations, and soft tissue injuries (see also Section 8: The Trauma Patient). Human burn patients have also been noted to have a significant decrease in overall immune function making them more susceptible to infectious disease and recrudescence of chronic viral infections. In avian species, this should also be considered and the patient should be closely monitored for additional comorbidities such as underlying bacterial, fungal, or viral conditions. Ectoparasites should also be assessed and treated accordingly (see Chapter 9). A thorough ocular examination should also be performed due to the high risk of corneal ulcers and conjunctival irritation from the smoke.

Once the patient is stabilized, the traditional steps of burn care, decontamination, wound assessment, cleansing, debridement, and dressings, should be implemented.

Decontamination

Decontamination of burn patients is essential to remove ash and associated carcinogens, as well as improve visualization for assessment of their injuries.[34] Veterinary and animal care personnel should wear gloves and wipe down patients with decontamination wipes (e.g., Hero Wipes) to minimize exposure of carcinogens. If decontamination wipes are not available, adult cleansing wipes are safe and can remove the superficial layer of soot until such a time the animal can be bathed. If no open wounds are present, the bird should be bathed with dish soap and rinsed thoroughly. This may need to be performed several times. If large wounds are present, the cleaning can be done with chlorhexidine gluconate (2%) mixed with water or saline to create a 0.05% solution and thoroughly rinsed clean.[35] Ideally all debris should be cleansed from the animal, but this should also be balanced with the level of stress this will incur.

Wound Assessment

After cleaning the area, the skin should be assessed for burns. Burn wounds can be difficult to fully classify early in appearance and can range from erythema to charred tissue. Mild burns that affect just the epidermis are often noted by redness of skin with normal texture. These are typically superficial or "first-degree" burns and generally will heal with no secondary complications. Partial-thickness or "second-degree" burns extend into the dermis. These can be noted by sloughing of the skin ranging from mild blisters (superficial partial thickness) to thickened and blackened areas (deep partial thickness). Deep partial-thickness burns can be difficult to differentiate from full-thickness burns without histopathology.[36,37] Partial-thickness burns will retain some of the feather follicles and typically heal in shorter time frame than full-thickness burns. Full-thickness burns due to high-intensity heat result in the loss of epidermis and dermis including feather follicles. These burns can extend down to muscle and bone and take months to heal depending on the location and size.[6,37] Similar to other wounds (see Chapter 36), thermal damaged skin will declare itself approximately 5 to 7 days after the injury, but burns also have a second phase that can result in further tissue loss 10 to 14 days postinjury due to areas that have suffered vascular ischemia.[36] Therefore it is essential to ensure good vascular perfusion and adequate hydration in these patients.

Cleansing

Gentle washing and thorough lavage of the wounds are essential parts of burn wound care. This can be performed via irrigation technique using saline or water. There is no proven validity in using sterile saline/water versus tap water.[38,39] The main factor is the amount of volume and mechanical irrigation that is utilized to comprehensively clean the wound of debris, microorganisms, superficial slough, exudate, and residual dressings from previous bandage changes.[5] Irrigation techniques can be performed using a syringe, a bottle with holes, IV line setup with catheter, a shower head, or a hose depending on the size and extent of the wound. Antiseptic solutions can be used in addition, but there is no evidence of beneficial impact on prevention of infection or improved healing.[40] Antiseptic cleansers such as chlorhexidine solution should be followed with extensive rinsing with saline or water to ensure no residual solution is left on the wound, as this can have cytotoxic effects on healing tissue.[41–44] The use of hypochlorous acid has also been evaluated in humans and seems to hold promise as a good antiseptic cleanser that has no residual cytotoxic effects if left on the skin.[45,46]

Debridement

Once an area of skin is thickened, blackened, with no blood flow, it is deemed an eschar. This tissue is no longer viable and should be removed.[37] Early excision is the current standard of

care in human medicine, with full removal down to viable tissue within 24 hours. Delay in removal of the eschar can result in a nidus for increasing local and systemic inflammation, infection, and ischemia. Human research has shown markedly improved morbidity and mortality with the use of early excision.[5,36,47] Removal of the eschar within 24 hours is not always possible in avian patients but should be performed as early as possible to prevent further risk of sepsis.

In human medicine, it is also the standard of care to perform escharotomies in burned areas that are at risk for increased compression that may inhibit arterial flow. Full-thickness eschars can tighten as they dry out, and the ongoing inflammation and swelling of underlying tissues can together result in severe compression of vasculature. This is most commonly seen in areas suffering from circumferential burns such as along the limbs. An escharotomy is the act of incising the full-thickness eschar to allow tissue decompression and it can be performed on each side of the circumferential burn depending on the location (Figure 53.3).[37,48,49] This procedure has not been well established in veterinary medicine and further evaluation in birds is needed. With minimal subcutaneous tissue in birds, the risk of circumferential constriction due to full-thickness burns is significant. Based on the authors' experiences, escharotomies in birds should be considered in extensive burns to the limbs noted by marked erythema, bruising, dried or dead skin, or if the toes are cool to the touch. Several ground-dwelling birds were euthanized due to secondary limb ischemia from burn constriction in recent fires and limb amputation has been noted as one of the complications seen in wildlife.[1]

Removal of the eschar and wound debridement can be performed using sterile gauze or surgical excision. The key with debridement is to remove the abnormal tissue down to tissue that is viable and has adequate blood supply.[36] Debridement is essential to not only remove the dead tissue but also to disrupt the biofilm that can develop on wounds.[50,51] Enzymatic debridement is also possible, but human products have not been fully evaluated in avian species and pain can be associated with the use of some of these products.

FIGURE 53.3 An escharotomy is the act of incising a full-thickness eschar to allow tissue decompression. It can be performed on each side of the circumferential burn, depending on the location.

Dressings

The choice of wound dressings can often be challenging and there are numerous products on the market (see Chapter 36). Unfortunately, despite the ongoing research, there is no perfect wound dressing for every individual during their entire wound healing process. Wounds must be continually assessed to determine the right dressing for the wound. The dressings should be modified depending on the wound severity (depth), location, amount of exudate, time frame since injury, and the individual patient. In addition, the cost and availability of the dressing should also be considered.[5,52–55]

The ideal dressing should provide pain relief, prevent contamination, reduce dryness, and maintain body heat. The loss of the skin barrier, depending on the depth, can leave patients vulnerable to infection and mechanical injury, susceptible to loss of fluid and protein, as well as decreased thermal regulation. Therefore dressings should be considered essential for all wounds with partial (second-degree) to full-thickness (third-degree) burns.[5,36,53] It has also been noted that keeping a burn wound covered with an appropriate dressing is one of the most effective pain management treatments due to the relief of covering exposed nerve endings.[56–58]

Primary dressings are applied directly to the wound and are often followed by secondary dressings made up of bandage material. Depending on the stage of wound healing, level of exudate, and the potential for infection, primary dressing can range from topical ointments to skin grafts. Wounds in birds are often minimally exudative and so maintaining an appropriate moisture layer is vital to healing. The most common primary dressing in veterinary medicine is a topical ointment/bandage.[53] Petroleum-based dressings such as Adaptic (Adaptic, 3M Corporation, St. Paul, MN, USA) are commonly used with one to two bandage layers to help moisturize dry wounds and create a conducive environment for healing.[59] Unfortunately, these dressings are not always ideal for avian species due to the excessive oil and they do not have any antimicrobial activity. Hydrocolloid dressings such as Intracyte gel and Duoderm are also good choices to help moisturize wounds and the structure of the polymers in some hydrocolloid topicals can assist with mild debridement.[54] Hydrocolloids can be used along with or incorporated with other agents such as honey (Medihoney HCS) or silver.[54,60] Unlike human medicine, animals are often delayed in being seen for burn care and frequently have a high probability of infection. Therefore it is recommended that the ideal topical ointment for avian should also have some antimicrobial activity. Antibiotic ointments are not recommended due to the risk of creating resistant bacteria[37] and if treating domestic poultry and waterfowl, regulations on the use of antibiotics in food-producing animals must be followed. Any topicals with corticosteroids should also be avoided due to the potential for infection in the face of burn-related immunosuppression.[61,62] The standard of care has been the use of silver sulfadiazine (SSD) for burn wounds and is still the most frequently used in

wildlife.[1] SSD does have antimicrobial properties that will penetrate through damaged tissue and makes it ideal for using in the field on eschars.[37,63] Once a wound is debrided, SSD should not be used as it has been shown in multiple studies to cause cytotoxicity and significant delays in wound healing.[63–65] If SSD is applied prior to debridement, it should be used with secondary bandaging layers so as not to be ingested by the bird. Other common antimicrobial primary dressings include honey and other silver-based wound dressings. The use of honey is increasing due to its relatively low cost and benefits in wound healing. Honey has been shown to have not only antimicrobial properties but also antiinflammatory and chemical debridement effects. It has a high sugar content that creates an osmotic gradient and it also stimulates leukocytes to aid in wound repair. Studies have also shown honey to have significantly faster healing time than SSD and other topical ointments.[66–69] Other synthetic silver-impregnated dressings are also available including Mepilex AG, Microlyte AG, and Silverlon. Many of these products have shown good antimicrobial activity, improved wound healing, and less silver cytotoxic effects.[63,70] These treatments are also labeled for >48-hour antimicrobial activity in humans[71] but have not been evaluated for duration of activity in birds.

In contrast to topicals and other synthetic primary dressings, biologic dressings have been investigated and found to provide better pain relief and improved wound healing.[5] Biologic dressings include autografts, allografts, and xenografts. The ideal wound treatment is the use of a patient's own skin (autograft) as a partial- or full-thickness graft. This is the standard of care in human burn patients but requires a fully debrided and clean wound with minimal movement postsurgery. It also creates an additional wound on the patient that will require ongoing wound care and requires surgical expertise to have the best success for graft survival.[7,63] In many circumstances, an autograft is not possible. The next alternative is an allograft, which is skin from a different individual but from the same species. These are usually donated from cadavers, sterilized, and preserved for use on human patients who cannot have an autograft.[72] Stored allografts for birds are typically not available and this makes this option unlikely. The most cost-effective option that is more readily available is the use of xenografts, skin that is harvested and preserved from another species. The most commonly used xenografts in human medicine include porcine and bovine. The benefit of the xenograft is that it not only functions as a skin barrier to provide pain relief and protection but it also provides a collagen matrix to facilitate wound healing.[73–75] The cost for several brands of xenograft has been out of the reach of the veterinary market. Recently tilapia and codfish have been utilized in several published and currently ongoing studies.[76,77] The fish xenografts are more affordable and in the authors' experience have been a good alternative for burn wounds in birds (Figure 53.4). More studies are needed, and the market of primary dressing continues to grow with new research developments in this area.

Secondary dressings are synthetic materials that can be used on top of primary dressings to add additional security or help the wound environment by absorbing excessive exudate. Dressings can include foam or silicone pads, with additional roll gauze, Vetwrap, or Elasticon, depending on the location and the need to secure the bandage. Some primary dressings can be applied without a secondary and should be considered for areas that are not conducive to full bandaging.[52,53,78]

FIGURE 53.4 A tilapia xenograft was used to cover this large wound in a northern bald ibis *(Geronticus eremita)*. Recently, tilapia and codfish skin have been used for the care of burns and other wounds in birds, increasing between-treatment intervals compared with commercial dressings.

Prognosis

Overall prognosis for avian patients with burn injuries can be difficult to determine and depends on the systemic insult and extent of injuries. In human medicine, the depth and amount of total body surface area burned are significant factors in survivability.[7,36,79] In addition, the presence of clinical smoke inhalation or other systemic comorbidities such as renal failure can greatly impact the possibility of recovery.[6,80]

Long-term recovery and the possibility of return to function should also be considered especially for wild avian patients. In a recent study of burned wildlife seen by rehabilitation centers, over 61.4% of animals with burn injuries presenting for care were avian and 41% of the animals presenting went on to full recovery and release.[1] Potential long-term complications noted included scarring, feather loss, self-trauma, sepsis, amputation, behavior issues, and pressure sores.[1] Birds can go on to have full recoveries, but the potential complications should be considered and they should be continually assessed during the recovery period. The occurrence of large-scale wildfires continues to be the new normal in many parts of the United States and throughout the world.[81,82] We are only at the beginning of learning the best ways to treat avian patients and further research is needed to continue to advance the tools needed to provide the best care for burn-injured animals.

CHAPTER 54

Wild Birds, Cats, and One Health

INTRODUCTION

For about 10,000 years, cats have lived alongside humans. Their relationship with prey species, including birds, is much older than that. Hunting, catching, and killing are their telos (a function, a set of activities intrinsic to an animal, evolutionarily determined and genetically imprinted, originally conceptualized by Aristotle).

The purpose of this chapter is to explore the effects of cats, particularly feral cats, on birds, bird populations (particularly sensitive species), and the ecosystems on which they (and we) depend. It includes some brief comments on the treatment of birds injured by cats and examines the role of the veterinarian in preventing impacts on wild birds. In keeping with the emphasis in this volume of *Current Veterinary Therapy in Avian Medicine and Surgery*, we discuss this in a conservation and One Health context.

HISTORY OF AN INVASIVE SPECIES

Domestic cats *(Felis catus)* have long been common in urban and suburban areas throughout the world, and the number of cats is continuously growing.[1] In contrast to dogs *(Canis familiaris)*, relatively few cat owners in the United States (25%–50%) mark or confine their cats to an indoor lifestyle,[2,3] contributing to the numbers of stray and homeless cats and to predation on birds and small mammals. Homeless domestic cats may be unfriendly, stray, or somewhat or very tame, but their impacts on wildlife and the environment are similar. Cats can have more than two litters of four or more kittens per year,[4,5] and availability of food leads to increased survival of kittens, and movement of cats across landscapes.[6] In many landscapes, particularly those devoid of predators, the high fecundity and recruitment of cats (survival until adulthood) allow for rapid increase in, and maintenance of, large populations. Where they are subsidized with food, cat densities of 229 to 523 cats/km^2 have been recorded in an urban area of the UK, far higher than native mesopredator densities (averaging 37 animals/km^2 for red foxes).[7] Cat densities have been recorded as high as over 2,000 cats/km^2 in sites in urban Rome, Jerusalem, and Ainoshima, Japan.[8]

Cats evolved in Europe, North Africa, and Asia, but no similarly dexterous and fecund mesopredator was present in North America, Australasia, or Oceania prior to human colonization. Annual surveys by the American Pet Products Association have documented that cats have surpassed dogs as the most popular companion animal in most of North America and Europe,[9] with the number of pet cats in the United States being estimated to lie between 80 and 90 million individuals.[1] The number of feral cats is unclear but estimated at approximately 480 million worldwide, with numbers in the United States and Europe estimated to be in the tens of millions,[10,11] and between 2 and 6 million in Australia.[12] Such large populations of both owned and feral cats have negative implications for wildlife and public health,[13,14] and there is broad interest from community groups, nonprofit organizations, and governmental agencies in reducing free-roaming cat populations.

Biologically effective, yet socially acceptable, management strategies for feral cats are a matter of contention in the United States and other countries.[15] In locations with imminent conservation threats due to cats (islands, protected areas, wildlife refuges, restoration areas), trapping and removal, shooting, poisoning (in Australia), and other lethal methods may be used by government agencies to manage feral cats.[16,17] Feral cat management in cities and towns has typically involved animal shelters and related organizations capturing and either socializing for the purpose of adoption, or euthanizing, unwanted feral cats. Citing a lack of success at decreasing cat populations, approximately 30 years ago animal shelters began using a new approach of trapping cats, sterilizing them, often cutting off the tip of one ear for identification, and releasing them back to the site of capture (trap-neuter-release [TNR]).[18] Most often these cats are supplementally fed, although their caregivers do not consider themselves as owners, or take the responsibility expected of owners. Today, TNR (or TNVR if vaccinations are provided) is popularly promoted by several nonprofit and lobbying organizations, despite the problems it poses for wild birds and other wildlife, environmental and public health, and the welfare of the cats themselves.[1] TNR will be examined in further detail below.

ONE HEALTH

As noted in the introduction to this section (Chapter 48), the veterinary profession has seemingly accepted One Health as

an organizing principle, even if some of our activities fail to adequately balance impacts on animals, people, and the environment. This is particularly true regarding the management of cats, and comments on One Health will be found throughout this chapter. One Health is a central concept of the Canadian Veterinary Medical Association position statement on free-roaming and abandoned feral cats.[19]

IMPACT OF FERAL CATS ON BIRD POPULATIONS

Wild bird populations deliver many critical ecosystem services, including but not limited to insect control, seed dispersal, pollination, nutrient distribution, and critical roles in many food chains, and therefore are an important environmental component of One Health. Cat predation and cat diseases are well-documented major mortality factors for birds and small animals worldwide. Ecologists and conservation biologists are most concerned with the direct impacts of high numbers of feral cats on populations of native birds and other small wildlife, as well as competition with native predators for food, and degradation of ecosystem health and stability.

Cats are instinctive hunters whose prey drive is not connected to satiety centers in the brain.[20] The number of prey that cats capture is not influenced by the number of meals provided.[21] Domestic cats continue to hunt during periods of supplemental feeding, and feeding does not decrease hunting.[22] Even well-fed cats hunt and kill wildlife (Figure 54.1).

Predation studies have shown that feral cats from colonies in Georgia, USA, exhibited more hunting behavior compared to pet cats.[23,24] Sterilization did not affect the cat's motivation to hunt.[25] Birds and other wildlife face many threats, some of which are difficult to predict and prevent (e.g., extreme weather events, emergent diseases), but impacts from invasive species like feral cats are generally predictable and preventable.

Free-living cats pose a significant population-level threat to the birds, herpetofauna, and small mammals they prey upon.[17,26,27] Cats have been implicated in extinction of 63 species on islands (40 birds, 21 mammals, and 2 reptiles),[28] but also have negative impacts on songbirds in continental environments.[7] An intensive investigation of the impact of feral cats on migratory songbirds at three study sites in Southern Michigan estimated that cats killed 0.7 to 1.4 birds per week of 23 species (including two species of conservation concern), equaling 12.5% of all species.[27] It was estimated that feral cats kill 16,000 to 47,000 birds in these three study areas per year. Over the past decades, similar rates of predation and loss have been recorded by studies all across the world.[29–31]

A broader estimation of the impact of free-roaming cats on the wildlife of the United States suggests that cats kill between 1.3 and 4.0 billion birds, and between 6.3 and 22.3 billion small mammals annually.[32] Feral cats are responsible for a greater proportion of kills than pet cats, which may be related to the increased amount of time spent outdoors. Mortality on this scale can be significant at the population, regional, or flyway level, especially for rare and sensitive species. Particularly vulnerable are species that forage on the ground (e.g., quail, woodcock, rails, thrashers, towhees) and species that nest on the ground (e.g., terns, plovers, shearwaters). These losses can have ecological consequences that are hard to reverse, even with the removal of cats. For example, the loss of seabirds (most of which are ground nesters) can result in the loss of nutrient (nitrogen and phosphorus) transport from oceanic to continental locations, a vital ecosystem service.[33] In Hawaii, feral cats have major negative impacts on endangered 'Ua'u or Hawaiian petrel (*Pterodroma sandwichensis*; Figure 54.2)[34] and are of concern to at least 13 additional threatened, endangered, or endemic birds.[35] Regardless of whether in continental or island ecosystems, cat-caused injury and mortality affect birds by altering population dynamics. Cat kills can exceed the ability of native species to

FIGURE 54.1 Well-fed cat killing a yellow-rumped warbler *(Setophaga coronata)* at a bird bath in Fair Oaks, CA, circa 2003. (Photo courtesy D.A. Jessup.)

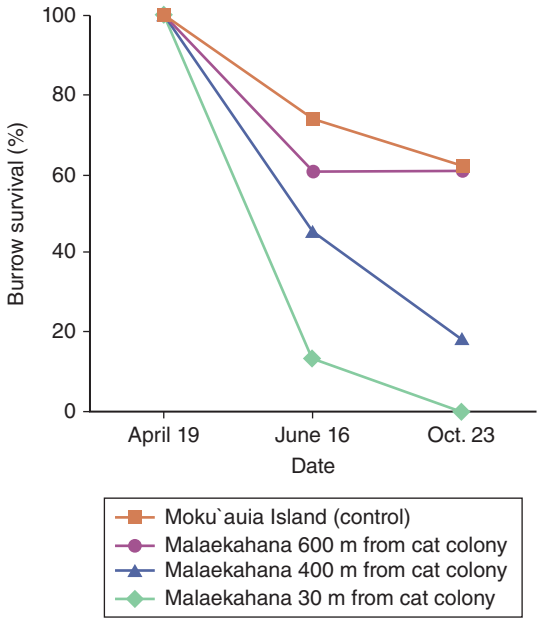

FIGURE 54.2 The serious negative impacts of feral cats on petrels and other ground-nesting seabirds in Hawaii have been well documented, in this case, the relationship between survival of petrel chicks in burrows and adjacency of feral cat colonies. Similar effects occur with other ground-nesting and ground-feeding species in both insular and continental habitats. (Courtesy D. Duffy.)

replace themselves, affecting the persistence of native wild bird populations.[36]

Cat diseases and parasites can have population-level effects on wildlife. Toxoplasmosis has been documented as a cause of death in many avian species, including passerines, doves, wild turkeys, and various diurnal and nocturnal raptor species. In Australia, the direct lethal effects of cats on endemic birds, reptiles, and small marsupials[37] are exacerbated by the high sensitivity of endemic species to lethal effects of toxoplasmosis.

IMPACT OF FERAL CATS ON WELFARE OF WILD BIRDS AND SMALL ANIMALS

Wildlife rehabilitation continues to gain popularity, with National Wildlife Rehabilitators Association (NWRA) membership growing from approximately 200 to >2,000 members since 1982. Notably, the subset of NWRA members responding to a member survey reported treating nearly 115,000 animals in 2007 alone,[38] which is certainly an underestimate given time passage and the survey's response rate. Birds and other small animals suffer from painful, debilitating, and often fatal injuries inflicted by feral cats.[39] Just as the welfare of cats is an issue for the veterinary profession, the welfare of all the species they negatively impact is also a serious welfare issue.

In 2004, feral cats were responsible for 24% of birds, 12% of mammals, and 15% of other species out of 5,669 wild animals presented over a 9-month period at a wildlife care facility in California.[11] Many of these injured wild animals were euthanized due to the nonrecoverable nature of their injuries, whereas others died from trauma or sepsis. More recently, a wildlife clinic in Tennessee reported cats to be among the top anthropogenic causes for submission of injured animals, responsible for almost half of the avian cases, of which the majority (around 70%) either died or were euthanized.[40] Interactions with cats was the second-greatest cause of small-mammal admissions to the Wildlife Center of Virginia over a 10-year period.[41] Moreover, data from 82 wildlife rehabilitation centers throughout North America found that, during a 3.5-year period, greater numbers of birds than reptiles, amphibians, or mammals were admitted for rehabilitation as a result of domestic cat attacks, and 78% of these did not survive.[42] The majority of immature animals admitted because of cat attacks also died or had to be euthanized because of the severity of injuries.[42]

When birds present for veterinary care and cat attack is suspected, standard principles of triage and emergency care should be applied (see Chapter 34). Obvious punctures and lacerations will require flushing, debridement, antimicrobials, and meticulous wound care. Cat bites often cause large skin lacerations, degloving, and/or crushing injuries. But, even if the bird is not bleeding and appears to be stable, it is imperative to perform a thorough examination to look for hidden puncture wounds by parting feathers carefully (Figure 54.3), and thoroughly searching for wet feathers, feathers caught in skin, and/or bruising. Thin and mobile avian skin can seal over puncture wounds quickly and, as a result, obscure deep wounds that can lead to sepsis, which may connect to internal injuries or massive hemorrhage, and death. Hence, if a cat bite is suspected, broad-spectrum antimicrobials are often given to prevent sequelae such as sepsis.

FIGURE 54.3 This mourning dove *(Zenaida macroura)* was admitted after a history of cat attack. Physical examination findings included multiple puncture wounds, including the one shown in the left pectoral muscle, and all the remiges on the left wing were missing. Close examination of birds attacked by cats is required as wounds may not bleed excessively, and small punctures and lacerations may only appear as wet spots or displaced feathers. (Photo courtesy Heather Barron.)

ECOLOGICAL AND ECONOMIC IMPACTS

As noted, many birds are consummate insectivores, seed dispersers, and nutrient recyclers. It is hard to overstate the negative impacts on ecosystems[43] and One Health due to anthropogenically caused declines in many bird populations. North American ecosystems and species did not evolve with medium/small feline predators (as opposed to larger bobcat, lynx, and mountain lion). As efficient small- to medium-sized predators, cats compete for prey with native mesopredators (e.g., hawks, owls, roadrunners, foxes, raccoons, skunks, opossums, weasels).[44] This predation is particularly impactful in developed, disturbed, or fragmented habitats. In places where native predators are reduced or absent, free-roaming cat numbers can increase markedly due to mesopredator release,[2] or simply by being the only mammalian predator, as is the case in a number of island ecosystems (e.g., Choiseul, Guadalupe, Hawaii, Mangere, Stephens, Stewart, etc.).

Economic impacts of events or activities (e.g., oil spills, wildfires, or development) that kill wildlife or degrade their habitat have recognized overall costs to society. One of the very few studies to consider the economic damage posed by feral and outdoor cats in the United States, conducted over 20 years ago, estimated the cost at $17 billion/year.[45] This dollar value was based on the estimated annual mortality to birds in the United States, which, at that time (1999), was conservatively estimated to be eight birds per cat per year,[46] multiplied by an estimated feral and free-ranging cat population of 71 million, and $30 per bird killed.[45] An updated

valuation of the damage caused by feral cats in the United States using a different approach estimated the cumulative costs over the past 60 years at $45.5 billion, with cats being the costliest invasive species in the nation.[47] Economic valuations may be challenged, but $30 is much lower than veterinary care costs for surviving birds, or legal penalties for harming endangered or migratory birds.[48] If updated with more current estimates of bird mortality from nonowned cats, it is between 952 million and 3 billion birds for the continental United States per year,[32] a more current economic loss estimate could range from $28.6 to $92 billion per year.[49] Importantly, this is only for birds.

Cats are the most common domestic animal source of rabies exposure,[50,51] and the species most commonly responsible for human postexposure prophylaxis (HPEP). Even though feral cats in managed colonies may receive a rabies vaccination when sterilized, they do not receive boosters, and records are generally not kept. So, when a person is bitten or scratched by a feral cat, they invariably must go through HPEP, which has significant costs ($20,000 – $30,000) and inherent medical risks. Public health agencies do not keep data on whether cat contacts resulting in rabies exposure involve feral or owned cats, but news stories over the last decade suggest this could be important and useful information. The economic costs associated with the several other cat-zoonotic diseases discussed later have never been estimated but, in aggregate, could easily approach the yearly economic losses for direct bird mortality.

ONE HEALTH AND DISEASES OF CATS

Diseases harbored by cats, particularly feral cats, can negatively impact the health of other animals and humans, posing a significant threat to One Health. Cats are carriers, reservoirs, or shedders of pathogens, including but not limited to *Bartonella henselae*, *Toxocara cati*, *Toxoplasma gondii*, typhus, tapeworms, hookworms, rabies, and feline leukemia virus.[52–55]

Toxoplasma

Toxoplasmosis has been found from the Arctic to the tropics across terrestrial, aquatic, and marine ecosystems and affects all homeotherms.[56] *T. gondii* in cat feces led directly to the extinction in the wild of the ala'la (Hawaiian crow; *Corvus hawaiiensis*).[57] Mortality due to toxoplasmosis also affected the recovery of nēnē or Hawaiian geese *(Branta sandvicensis)* and red-footed boobies *(Sula sula)*,[58] and is an important cause of death in the endangered Hawaiian monk seal *(Monachus schauinslandi)*,[59] and other listed or sensitive marine mammals including Southern sea otters *(Enhydra lutris nereis)*,[60] and two species of manatee.[61,62]

Felids are the definitive host and the only species shedding *T. gondii* oocysts in their feces. An estimated 40 million human beings are infected with *T. gondii*, and it is considered a leading cause of death attributed to foodborne illness in the United States.[63] Worldwide, approximately 40% of *T. gondii* exposures appear to be the result of oocyst contamination of water or soil, thus directly the result of cat feces in the environment. Ingestion of bradyzoites in undercooked meat accounts for about 60% of infections worldwide, but only oocysts can survive in the environment, so even ingestion of bradyzoite tissue cysts begins with fecal shedding of oocysts by felids. In the United States, most human infections are from oocysts, not ingestion of bradyzoites, based on the sporozoite-specific enzyme-linked immunosorbent assay (ELISA).[64] Feral and free-roaming cats in coastal communities can be a significant source of oocysts that wash directly into the ocean.[53]

Bartonella

B. henselae, the cause of cat scratch disease, usually results in a self-limiting regional adenopathy. But more serious sequelae are common, and it is now considered an occupational hazard for the veterinary profession. In 1994, five Florida children were hospitalized with encephalitis associated with cat scratch fever.[65] The oral flora of cats, above and beyond *B. henselae*, is notorious for causing difficult-to-treat local and regional infections (due to *Pasteurella multocida*, *Staphylococcus* spp., and *Streptococcus* spp., etc.).

Rickettsia

A daycare center at the University of Hawai'i at Mānoa was closed for 2 weeks in 2002 because of concerns about potential transmission of murine typhus *(Rickettsia typhi)* and flea *(Ctenocephalides felis)* infestations afflicting 84 children and faculty.[66] The fleas were from a feral cat colony that had grown from 100 to over 1,000 cats, despite a TNR effort.[66] Similar situations have been reported in Southern California and Texas housing complexes where high populations of subsidized feral cats and rats coexisted.[67]

Hookworms and Roundworms

In Florida, one study found approximately 75% of feral cats to be positive for the feline hookworm *Ancylostoma tubaeforme*, whereas 33% were positive for *Ancylostoma braziliense*.[68] In 2010, an outbreak of hookworm (cutaneous larva migrans) was reported in people (Figure 54.4) who had visited beaches in Miami-Dade County, FL.[69] Feces from feral cat colonies along the beachfronts were the putative source. In 2006, 22 cases of cutaneous larva migrans were reported in children at a summer camp due to cat feces in sand boxes.[70] Similar circumstances can also lead to the more serious visceral larva

FIGURE 54.4 A case of cutaneous larva migrans due to feline hookworm *(Ancylostoma)* presumed to be the result of contact with feral cats' feces on a Florida beach. (Photo courtesy Scott C. Sherman, Department of Emergency Medicine, Cook County Hospital (Stroger), Chicago, IL.)

migrans in humans caused by the migrating larval stages of the common cat roundworm, *T. cati*.

Feline Leukemia Virus

Cats can serve as reservoirs for significant pathogens that affect other wildlife, such as feline leukemia virus (FeLV), which was found to be transmitted from feral cats to the endangered Florida panther.[71] A similar case was reported in a mountain lion in California.[72] The problems *T. gondii* poses to marsupials (and many other species) have been mentioned, so establishing feral cat colonies at or adjacent to zoos is a concept whose direct (predation) and indirect (disease) consequences for captive and free-living wildlife, and public health, may be quite problematic.

OUTDOOR AND FERAL CAT MANAGEMENT

Many veterinarians advise cat owners that their animals are safer indoors. However, a double standard exists regarding feral cats as the follow-up care they receive usually falls far short of standards in feline practice. Clients with indoor cats may experience behavioral problems; hence veterinarians need to provide information on enriching cats' lives and how to provide opportunities for supervised outdoor time. In 1997, the American Bird Conservancy (ABC) launched *Cats Indoors*, a program focused on protecting both birds and cats. The ABC Cats Indoors website contains excellent updated instructions and specific recommendations.[73] An increasing number of cat owners are keeping their cats indoors or are exploring a variety of safe and sensible ways to permit them supervised or controlled outdoor time. Indoor-only cats also have fewer diseases and parasites that are harmful to cats and people.[74] Outreach has resulted in a growing number of cat and non–cat owners demanding that municipalities enact and enforce ordinances promoting responsible cat ownership, something that has been in place for dogs for decades.

"Belling the cat" has been around for hundreds of years and may have some efficacy in warning birds and small animals of the presence of a predatory feline, despite ambiguous results in published studies.[75–77] Studies show that antipredation devices may reduce (but not eliminate) the number of prey brought home.[78] The mere presence of free-roaming cats, however, can reduce avian fecundity,[79,80] and orphaning of nestlings continues. Furthermore, cat bibs, flashers, or bells on collars do not protect pet cats from vehicles, predators, fights with conspecifics, trauma, poison, or extreme weather conditions. As a result, these devices should not be considered a substitute for keeping cats indoors and may give pet owners a false sense of accomplishment.

In North America, the responsibility for the management of unowned and stray animals generally resides with city, regional, and/or county animal control agencies. Traditional methods used to deal with stray and/or feral cats include: (1) capture and return to, or reclaim by, the owner; (2) public adoption; and (3) euthanasia. It should be noted that all three options are humane and viable, with reclaim/return facilitated by routine use of RFID chips. All three options remain available, and with modern enhanced communication and networking, animal control agencies can now assist one another with "cage space" to hold cats longer, or move them to locations where adoption is more likely.

TRAP-NEUTER-RELEASE

TNR for cats gained attention in the early 1990s, concurrent with the formation of Alley Cat Allies (ACA), a national cat-focused organization that today boasts a budget of $10 million. It was first promulgated as a population reduction method that would result in the eventual elimination of outdoor cat colonies. TNR-promoting organizations subsequently changed the goal to colony stabilization, or no new kitten births. Evidence of success of even these revised outcomes has been lacking. When these more modest goals did not succeed, some TNR promoters changed from reducing the numbers of feral cats to "saving" them, to emphasize avoiding euthanasia (touted as the only alternative and part of the "no-kill" movement) and maintaining feral cats in perpetuity.

The primary reasons that TNR (and its variants) does not work on landscape or large population levels are as follows: (1) people keep abandoning intact cats, often at known TNR locations, believing they can live free and/or will be taken care of; (2) it is nearly impossible to exclude immigration by intact cats, attracted by food, from peripheral areas; (3) the cat's inherently high reproductive capacity means that immigration of intact females, and those not yet sterilized, can produce kittens faster than they can be trapped; (4) it is very difficult to capture and spay the very high percentage of cats (75%–85%) required for population stabilization for at least 5 to 10 years; and (5) many TNR caregivers get discouraged after years without reduction of the cat population and quit. Hence, TNR programs do not function as an effective means to manage a population, but largely as a means to reduce intake at shelters and prevent euthanasia of homeless, unadoptable cats.

Population modeling has shown TNR to be less effective than simple removal.[4] TNR has been practiced at Stanford University for over 35 years with no decrease in cat numbers.[11] In summary, TNR, as commonly practiced, seldom stabilizes or reduces and almost never eliminates established feral cat colonies unless significant numbers are regularly removed.[6,81,82]

Although success or failure of feral cat TNR management programs can be monitored with easily collected data and statistical analyses, this is rarely done and is strongly resisted by most TNR advocacy organizations. An assessment of two large, sophisticated feral cat TNR programs in San Diego County, CA (n = 14,452), from 1992 to 2003, and in Alachua County, FL (n = 11,822), from 1998 to 2004, using field data in a Ricker mathematical model to describe population dynamics, showed that in both counties, there was no consistent reduction in per capita growth, the population multiplier, or the proportion of female cats that were pregnant.[81] To date, no published study has refuted these findings.

A very basic problem with TNR is that it is almost entirely cat-centric, or cat advocate-centric, with little or no consideration of wildlife, people, or the triad of One Health. Specifically, TNR maintains nonnative predators in the environment, essentially in perpetuity, with no diminished capabilities for injuring and killing wildlife. TNR does not stop the movement of diseases between cats and other animals (including people), thus creating perpetual health risks. Waste and spoiled cat food can attract wild birds and scavenging and predatory

FIGURE 54.5 Feral cat feeding stations attract scavengers such as rats and raccoon (A) and wildlife predators such as fox and coyote (B) as well as birds. This type of situation encourages pathogen jumps between species and is the antithesis of the One Health concept. Raccoon, fox, and skunk are important vectors of rabies in North America. Fights over food and injuries jeopardize the health of cats and people who may subsequently encounter them. (Photos courtesy Stefan Woltmann, Clarksville, TN, USA.)

mammals, including rats, as well as skunks, foxes, coyotes, and raccoons, some of the most important wildlife vectors of rabies in North America (Figure 54.5). Cat feeders and advocates are even willing to defy law enforcement efforts to limit the damage done when leftover cat food attracts endangered species like the nēnē goose in Hawaii.[83] Concentrating cats, their urine and feces, and that of closely related species creates an environment that encourages pathogens to jump between species, the antithesis of One Health management. However, nobody, not feral cat advocacy groups, caregivers, veterinarians, or pet food retailers who facilitate TNR, or agencies of government, is willing to take responsibility for, or mitigate, these serious problems feral cat colonies create.

TNR is not considered humane for cats by many experts. The most common causes of feral cat mortality in one California county were vehicle trauma, predation, disease, and/or severe weather (Figure 54.6).[84] People for the Ethical Treatment of Animals (PETA) have called TNR "subsidized abandonment" and state that "feral cats live short, hard lives on the streets." They never die of "old age."[85] The American Veterinary Medical Association (AVMA) has stated, "Free-roaming cats may be exposed to injury, suffering, and death from vehicles; attacks from other animals; human cruelty; poisons; and traps. Additionally, these cats are more likely to be exposed to feline-specific, and zoonotic diseases, and will prey on and can negatively impact native wildlife populations."

ALTERNATIVES TO TNR OR EUTHANASIA

Feral cat advocacy groups insist that there are only two alternatives: TNR or mass euthanasia. This is a "false dichotomy," a technique used in debate. Feral cat numbers are unlikely to decline unless multiple strategies are adopted in combination. A first step must be community commitment to greater responsibility for feral cats and significantly decreasing or stopping cat reproduction. Mandatory spay-neuter laws could be a start. Recently, it has been shown that a single injection of a feline anti-Müllerian hormone (AMH) transgene was sufficient to induce long-term contraception in female cats[86] and may be able to replace surgical contraception. But to be effective in feral and free-roaming cats, advances in contraception probably need to be orally active and cat specific to protect nontarget species.

Where TNR colonies exist, focusing on removing cats for adoption is a positive step that communities can take. In addition, strongly enforced, effective licensing, identification, and confinement laws are integral. Continued financial support for animal control agencies and shelters that are tasked to

FIGURE 54.6 The most common causes of feral cat morbidity and mortality are trauma from various sources (vehicles, predators, malicious people), severe weather, and diseases and parasites. This cat, whose clipped ear identifies it as being from a TNR program, was found on a highway median strip in Brevard County, FL. It had a fractured mandibular symphysis and other injuries and would have died of thirst and starvation, or additional trauma, if not rescued. It was not "wild," but it recovered and did fine as a pet. (Photo courtesy C. Strorts.)

FIGURE 54.7 Indoor-outdoor enclosed catios are commercially available, and larger barn-like versions, like this one in Chico, CA, have been used to house feral cats where free-roaming colonies once existed.(Photo courtesy L. Winter.)

remove, socialize, and adopt animals is also essential. In the last few years, networking among shelters has enabled the movement of unadopted cats between locations, alleviating overcrowding, decreasing pressure for euthanasia, and increasing opportunities for adoption.

Pervasive and consistent public education programs are needed to encourage responsible feral cat management, as well as pet ownership by promoting: (1) reproductive control of all cats; (2) awareness of the responsibility that TNR promoters have for the health and welfare of people and other animals; (3) keeping cats indoors or supervised while outdoors; (4) methods to practically achieve this; and (5) collective responsibility for owned and unowned cats, whereby reabandoning them is considered unacceptable. In addition, cat owners need to be shown examples of devices that—with varying levels of supervision—can be used to allow cats to enjoy the outdoors without harming wildlife (e.g., pre built and commercially available cat condos, flexible cat tunnels, harnesses, cat carriers, cat strollers). One of the intermediate potential solutions for replacing free-living TNR colonies is enclosed colonies. Enclosed colonies (sometimes called sanctuaries) provide all the benefits afforded by a managed TNR colony in an enclosed, typically outdoor space (Figure 54.7) and are safer for wildlife, people, and cats themselves.[87]

WHAT CAN YOU DO?

There is a great deal any veterinarian or conservation-minded person can do to educate the public about the pernicious effects of feral and free-roaming cats on wildlife, human and environmental health, as well as actions that can be taken or encouraged. They include, but are not limited to, the following: (1) standing up for one health; (2) not doing harm; (3) demanding responsibility; (4) promoting viable solutions to reduce harm to wildlife, human, and environmental health; (5) speaking out in public forums and with clients; and (6) being informed.

Stand Up for One Health

As has been noted in this chapter, maintaining cats outdoors is hard to justify under the One Health paradigm. Although the AVMA policy statement on feral cats acknowledges several of the negative consequences of outdoor cats to wildlife, public health, and the environment, it continues to assume that TNR and "community cat" numbers will decrease, despite little evidence to demonstrate that this is occurring on meaningful scales. Veterinarians who care about balancing the health of animals, humans, and the environment need to seek and promote solutions that cause the least damage to all and that resolve problems rather than making them permanent.

Do No Harm

If asked to participate in a TNR program, consider responding "only if the 'R' is not re-abandon." The AVMA encourages keeping cats indoors, both for their own safety and for the protection of wildlife. The Wildlife Society,[88] a 10,000-member organization of professional wildlife biologists (the wildlife biology equivalent to the AVMA), and many avian, aquatic, and wildlife veterinary organizations strongly oppose TNR, primarily because of the impacts on native species.

Demand Responsibility

AVMA's policy on feral cats states: "The goal of colony management should be continual reduction and eventual elimination of the colony through attrition… For colonies not achieving attrition and posing active threats to the area in which they are residing, the AVMA does not oppose the consideration of euthanasia when conducted by qualified personnel, using appropriate humane methods as described in the AVMA Guidelines for the Euthanasia of Animals." Yet seldom are TNR colonies, once established, monitored for reduction or elimination, and veterinarians who contribute to TNR have shown no willingness to be involved in seeing that this AVMA expectation is met.

Cat caregivers and their supporters need to be held responsible for killing and injuring wildlife and for the pollution caused by TNR colonies. They need to be responsible for feces, food waste, its attraction of rats and other vermin, garbage, and for the attraction of wildlife to a potentially lethal site. Where TNR is being practiced on public land or with public funds, the vital rates of the population, success or failure in stabilizing or decreasing numbers, costs and conflicts, and the fates of the cats themselves should all be documented. Continued irresponsible behaviors, either by individuals, organizations, or officials, may need to be legally challenged, as has occurred in Los Angeles and New York. Elected officials need to be reminded that protecting wildlife health and ecosystems, public health, and property, rather than just the interests of vocal cat protectionists and organizations, is their job.

Promote Viable Solutions That Reduce Harm to Wildlife, Human, and Environmental Health

Reducing the yearly reproduction of cats and promoting all social, legal, political, or educational efforts needed to accomplish that needs to be "Job 1" wherever you stand on feral cat issues. So, consider:

- Recognizing that free-living cats are nonnative, invasive small- to medium-sized predators in North America and harmful to ecosystems that support native wildlife.
- Supporting all efforts to educate the public not to abandon their cats: THEY ARE NOT GARBAGE.

- Supporting local and regional and local animal control efforts that emphasize adoption and that do not victimize wild birds and other animals, or help them change if they do.
- Recognizing that life and death on the streets and back lots is not really a caring or humane outcome for most feral cats themselves is very damaging and cruel for small wildlife, destabilizes ecosystems, and increases public health risk for several zoonotic diseases. TNR, as currently practiced, is not compatible with a One Health perspective.
- Insisting that existing TNR efforts be monitored for success, kept away from important wildlife habitat, and improved or closed if they fail to stabilize, then reduce cat numbers.
- Supporting early trapping and taming of feral kittens for adoption.
- Supporting increased efforts to tame, hold, and place stray and formerly feral cats, optimize cooperation and movement to utilize existing cage space, and reduce pressure for euthanasia.
- Supporting "Cats Indoors" and other efforts to reduce the impacts of owned and unowned cats on wildlife, environmental and human health.
- Supporting client-owned "catios" and considering where larger-scale cat sanctuaries might be used to enclose existing feral cats groups.
- Counseling clients to protect their cats, optimize their health, and reduce the many problems created by cats that are allowed to roam free.

Speak Out in Public Forums and With Clients

Veterinarians are well-respected members of the community and can have a powerful impact on the public with whom they interact every day, and at local government meetings where feral cat management strategies are often set. Engage with others who do not share your views and hold constructive discussions. Hopefully, all groups can agree that the ultimate goal is to have cats under the care of a person; safe from vehicles, predators, and harsh weather, and with preventive medical care; and away from wildlife they kill and maim.

Be Informed

Feral cat management is newsworthy, controversial, and a hard subject to stay current on. Not all publications are based on solid science or on comprehensive review. The authors of this chapter would like to draw the reader's attention to one recent comprehensive science-based review of the management of feral cats.[89]

CHAPTER 55

Falconry: Past, Present, and Future

INTRODUCTION

Falconry, also called "hawking," is the hunting or taking of game with trained falcons, hawks, eagles, and in some regions even with owls, although owls are excluded from the definition of falconry. A falconer is then generally defined as someone who keeps, cares for, trains, and hunts with hawks, falcons, and other birds of prey. In 2010, the United Nations Educational, Scientific and Cultural Organization (UNESCO) through the Convention for the Safeguarding of the Intangible Cultural Heritage recognized falconry as an intangible cultural heritage.[1] Falconry is so much more than a hobby or pastime. It represents knowledge, practice, experience, culture, traditions, expressions, arts, literature, social events, craftsmanship, and comradery transmitted from generation to generation through families, mentorship, and training.[1]

Falconry transcends gender, religious, political, national, and socioeconomic boundaries and is practiced on every continent except Antarctica. The cultural diversity within falconry is evident during the International Falconry Festivals, the first of which was held in 2007 at Engelhard Estate, United Kingdom (UK), and was the largest gathering in history. This and other events bring falconers together from around the world to experience the history, pageantry, comradery, and passion of falconry. A second festival was held in the UK in 2009, then Al Ain, United Arab Emirates (UAE), in 2011, and Abu Dhabi, UAE, in 2014 and 2017 (Figure 55.1).

The origins of falconry date back to more than 2000 BCE, originating spontaneously in the Central Asian Plateau, Persia, the Middle East (Arabia), then shortly thereafter in other parts of Asia (China, Japan, Mongolia; see sections on Falconry in the Middle East—The Past and Falconry in Asia—The Past).[2–4] In these parts of the world, falconry served a utilitarian purpose—literally to put food (meat) on the table. Falconry spread to Europe, particularly due to trade between Arabia, Europe, and the Far East and reached the Mediterranean near CE 400. In Europe and the UK falconry gained popularity as a sport of nobility, yet it was practiced by all socioeconomic classes (see sections on Falconry in Europe—The Past and Falconry in the UK—The Past). Unfortunately, the development of gunpowder and firearms in the 14th century caused a significant decline in the practice of falconry as raptors were then viewed as vermin, to be shot and killed.

At the core of falconry is the concern for the health and well-being of the birds of prey that falconers use. Frederick II of Hohenstaufen, Holy Roman Emperor, King of Sicily and

FIGURE 55.1 The Parade of Nations at the 3rd International Festival of Falconry, Abu Dhabi, United Arab Emirates, 2014. Under the patronage of His Highness Sheikh Khalifa bin Zayed Al Nahyan, President of the United Arab Emirates, and organized by the Emirates Falconer's Club and the Cultural Programs and Heritage Festivals Committee, the event featured a desert camp, a scientific program, cultural events, and educational opportunities for hundreds of falconers, representing over 80 countries. (Photo courtesy Mike Dupuy, used with permission.)

Jerusalem, was considered to be the greatest of all historical falconry aficionados. His text, *De Arte Venandi cum Avibus (The Art of Falconry)*, represents one of the first scientific literary works on avian anatomy,[5] and many consider him one of the founders of ornithology. Frederick II stressed the importance of hygiene, sanitation, good nutrition, exercise, and medical therapy to maintain the health of birds used for falconry. Now, with the advent of hospitals and rehabilitation centers around the world, specifically focused on the care of free-ranging raptors and those in managed care, the behavioral, medical, and surgical management of birds of prey is a distinct discipline in the field of avian medicine and raptor conservation.

In 1968, the International Association for Falconry (IAF) and Conservation of Birds of Prey was founded in Zweibrücken Hof, Düsseldorf, Germany, during the conference of the International Council for Bird Preservation (ICBP), with the following objectives: (1) to represent the art of falconry throughout the world, (2) to preserve and encourage falconry within the context of sustainable use of wildlife, (3) to encourage conservation, the ecological and veterinary research on birds of prey, and to promote, under scientific guidance, domestic propagation for falconry, (4) to develop, maintain, and amend national and international laws, treaties, and conventions to permit the pursuit and perpetuation of falconry, (5) to require the observation of falconry, hunting, conservation and welfare laws, regulations, traditions, and culture with regard to the taking, import, export, and keeping of birds of prey, the taking of quarry species, and the right of access to land in the country concerned, and (6) to promote and uphold a positive public image of falconry with specialist organizations that regulate or otherwise affect falconry.[6]

Falconry is constantly evolving and characterized by innovation in all aspects of the activity including behavior and health care, introduction and use of new species of raptors, and innovative training methods using kites, drones, radio-controlled aircraft trailing lures, and even radio-controlled aircraft that resemble other avian species. The practice of falconry may vary around the world; however, a common theme among falconers is the preservation of natural resources, conservation of birds of prey and their habitats, and a close association with the raptors they use for this activity.

Much of the language used in falconry originates from the Latin-French language. Many falconry terms are now used in the modern English language, with many people unaware that their origin comes from falconry. Confusingly for people new to the sport, some words like "cast" have multiple definitions depending on the context used. A glossary of common falconry terms (in the English language) is included in the chapter (Table 55.1). It is important for a veterinarian treating falconry birds to have an understanding of the language used so an effective husbandry and medical history can be obtained.

TABLE 55.1
Glossary of Common Falconry Terms (in the English Language)

Term	Definition(s)
Accipiter	True hawk or shortwing. Short, rounded wings and long tail give high maneuverability.
Austringer	A person who trains and hunts with hawks (accipiters). Originates from the Latin word for goshawk—astur.
Aylmeri	Leather anklets fitted around the bird's legs with eyelets through which jesses are threaded and removed.
Bate	To fly off the fist or perch. May happen with a keen hawk baiting toward the falconer or a nervous bird baiting away from an unfamiliar object.
Bewit	Thin leather strip used to attach a bell or other equipment to the leg of a bird.
Block	Solid flat perch with a padded (usually synthetic turf) top, for falcons and eagles.
Broadwing	Birds of the *Buteo* and *Parabuteo* genera. Broad wings are ideal for soaring flight.
Cadge	A frame—traditionally wood, but now often plastic—used to carry multiple hawks into the field.
Cast	A pair or group (similar to a pack) of birds flown together—common with Harris's hawks. Restraining the bird in the hands—during examination or when fitting equipment. When a bird ejects the indigestible portion of the food—called a casting or pellet. The act of propelling a bird forward off the fist to give some extra initial forward impetus.
Cope	To trim and shape an overgrown beak or talons.
Creance	A line used during the final part of training before free flight.
Deck feathers	The central pair of tail feathers—bells and telemetry are commonly attached to these feathers.
Eyass, eyess, eyas, nyas	A bird in its first season (<1 year age).
Follow-on	A hawk moving from tree to tree or perch to perch following the falconer.
Free lofting	A hawk being kept untethered in a mews or special weathering chamber.
Glove/gauntlet	Glove used when a falcon or hawk is sitting on the falconer's fist.
Hack	A period of free flight before being caught for training. Traditionally performed with eyass birds.
Hack back	A form of soft release used to release rehabilitated wild birds following treatment.
Haggard	A bird of prey caught after at least one molt.
Halsband	Light fabric collar used to attach a bell to a hawk's neck.
Hood	Traditionally a close-fitting leather head garment used to blindfold a bird to reduce stress caused by visual stimulus during training and sometimes traveling.
Jesses	Narrow straps of leather fastened around a bird's leg. Mews jesses have a slit end to allow attachment of a swivel. Field jesses are without a slit, which minimizes the risk of tangling in branches.
Imp/imping	Process of replacing a portion of a broken or damaged feather with another for feather repair.
Mangalah	A short cuff used by Arab falconers to hold the falcon on the fist.
Manning	A period where a bird is accustomed and desensitized to environmental stimulus.

TABLE 55.1
Glossary of Common Falconry Terms (in the English Language)—cont'd

Term	Definition(s)
Mantle	Where a bird stands over food or prey with wings and tail spread to hide it.
Mews	Derived from the French word for molt—mew. Mews are aviary-type buildings where birds are kept free-lofted or to molt.
Mutes	Droppings.
Passage hawk	An immature hawk caught during its first migration.
Slip	To release a hawk from the fist in pursuit of quarry.
Swivel	Rotating metal-ringed device for joining jesses to the leash.
Tyring	A bony piece of food designed to be time-consuming to eat—requiring a hawk to pick at the food (e.g., a head of a rabbit).
Wait on	When a bird circles above the falconer waiting for the quarry to be flushed.
Water pan	Bowl/basin for bathing and drinking.

FALCONRY IN THE MIDDLE EAST—THE PAST

> *The best falconer is not the one who hunts the largest number of houbaras, but the one who has the wisdom of leaving some for tomorrow.*
>
> **HH Sheikh Zayed bin Sultan Al Nahyan, President of the UAE (1918–2004)**

In the past, Bedouins across the Middle East used to trap, train, and hunt with migratory falcons to supplement their basic diet. The falcons were then released in early spring as it was not possible to keep and feed them during the summer months. Falconry has been part of life in the desert since ancient times.

Arabian academics have been able to establish that, in the Arabian Peninsula, falconry saw its early beginnings during pre-Islamic times in the Al Jaheliya era with Al Harith bin Muawiyah bin Thor bin Kindah. According to history, one day, while Al Harith was watching a man setting up a net to trap birds, a falcon appeared and attacked a bird already caught in the net, and the falcon became entangled. Al Harith marveled at this and ordered that the falcon be brought to him. He took the falcon to his house and appointed a servant to feed and train the falcon for hunting. In a short time, Bedouins became aware of the experiences of Al Harith and his falcon, and soon the trapping and training of falcons for hunting became part of life in the desert.[7]

Then came Islam. One of the most famous hunters during the period that witnessed the rising of Islam was the renowned Hamza bin Abdulmutallab bin Hashem (54 before Hejri–3 Hejri, CE 556–625). He was greatly admired for his courage and was dubbed "The Lion of God." It is said that he embraced Islam after returning from a hunting trip while holding a falcon on his wrist.[7]

In the ensuing period, falconry continued to flourish during the Al Umauwiya era in post-Islamic times. One of the most famous falconers of this era was the Caliph Yazid bin Muawiyah bin Abisofian Al Umauwy (26–64 Hejri, CE 646–683). Abu Al Hassan Ali Al Hussein Ali Al Masaudi once said, "Yazid loved music, birds of prey, salukis and cheetahs, and was an enthusiastic hunter, a sport in which he excelled. He was the first man to carry a cheetah on horseback."[7]

Yazid, when appointed Caliph of Damascus in 60 Hejri (CE 679), ordered the construction of falconry hunting lodges for his own personal use. Subsequent caliphs thereafter used these lodges. Caliph Hisham bin Abdulmalik Al Umauwy (92–125 Hejri, CE 710–742, appointment date 105 Hejri, CE 723) was also a keen hunter. While on a hunting trip, he observed his party from an elevated point. Some hunters used birds of prey, while others hunted with cheetahs, bows, and arrows. Later he commissioned a drawing of the hunt, where he and some of his aides were portrayed by the distinguished artist Al Ghatrif bin Khudama from the tribe of Ghassan. Hisham also instructed Al Ghatrif to care for his birds of prey. He was to train and prepare them for hunting and to cure them when they were ill. Hisham also bestowed upon him the title "Hunt Master of Hisham bin Abdulmalik." A special department was set up within his court to deal with issues related to his falcons and falconry.[7]

In the Al Abbasiya era, falconry rose to new dimensions with the influence of the Persians, who were well known for their ability to train and hunt with birds of prey. During the rule of the first caliph of the Al Abbasiya era, Abu Al Abbas As Saffah Al Abbasi (104–136 Hejri, CE 722–753), falconry continued to thrive, since As Saffah was very fond of birds of prey and a devoted hunter who practiced falconry from an early age. His interest and enthusiasm for hunting were legendary and he was a source of inspiration to all his people. Yet there were other eminent caliphs in this era with a great passion for hunting that promoted falconry to the status of art.[7]

During the reign of the 5th Caliph (appointment date 170 Hejri, CE 786) Harun Al Rashid Al Abbasi (148–193 Hejri, CE 766–809), individuals were summoned to explain a particular hunting skill they had developed. Al Rashid was already a skilled hunter, but he always had a keen interest in furthering his knowledge in a continuous quest for perfection. By this time, falconry was not only a well-established entertainment of the caliphs, but it was also considered an affair of the state. During the reign of the 6th Caliph (appointment date 193 Hejri, CE 808) Mohammed Al Amin bin Harun Al Rashid Al Abbasi (170–198 Hejri, CE 786–813), 1% of the total daily budget of the caliphate was allocated to maintain the sport of falconry. Thus salaries of up to 70 dinars a day were paid to falconers and falcon keepers.[7]

The first Arabic manuscript related to falcons and falconry, *Benefits of Birds and the Comprehensive Treatment of their Diseases*,

is believed to have been written by Adham bin Mahres Al Bahili during the reign of Caliph Harun Al Rashid Al Abbasi. In one of its sections, it says, "It was natural that the keeping of birds of prey and hunting birds should not be restricted to the Caliphs but that people in all walks of life should be able to do so as well." This was a manuscript composed of 153 chapters in which issues such as diagnosis and diseases were first described. This manuscript is believed to have been enriched by the participation of Al Hajaj bin Khaytamah during the reign of the Caliph Mohammed Al Amin bin Harun Al Rashid Al Abbasi. *The Animal*, one of the most famous treatises in Arab literature on animals of all times, was written by Amro bin Bahar bin Mahboob bin Kanani Al Jahiz (163–255 Hejri, CE 779–868). In his book, the famous author mentioned that Arab falconers preferred to hunt with saker *(Falco cherrug)* and peregrine *(Falco peregrinus)* falcons rather than with Eurasian goshawks *(Accipiter gentilis)*, although the latter were much in demand by Persians, Turks, and Indians at the time.[7]

At the end of this era, between the years 490 and 601 Hejri (CE 1096 and 1204), Arab falconry extended its influence over Western Europe. In this respect, two of the most important Arab contributions to European falconry included the hood and the use of the lure.[7]

Sadly, there was a crucial interlude in the continuing contribution of Arab literature to the history of falconry with the Mogul occupation of Baghdad in 656 Hejri (CE 1258). It has been estimated that Arab writers made approximately 30 publications on falcons and falconry between 287 and 391 Hejri (CE ninth century), at the peak of Arab cultural evolution, and 700 to 803 Hejri (CE 13th century), when the Abbasid Empire collapsed.[7]

Throughout the succeeding decades, falconry continued to decline in the domains of the Ottoman and Mogul empires, but falconry prevailed deep inside the immensity of the sands of the Sheikhdoms in the Arabian Peninsula.

FIGURE 55.2 In the Middle East, falconry is part of the cultural heritage passed from generation to generation. Fast cars and fast-food restaurants in a fast-changing world have displaced customs and traditions, but falconry remains deeply rooted in the heart of Arabs as a way of communion with the past.

FALCONRY IN THE MIDDLE EAST—THE PRESENT

Falcon Species Used in Falconry in the Middle East

In the Middle East, falconry has been practiced exclusively using falcon species since ancient times. The main reason for this tradition is that some falcon species, notably the peregrine, the saker, and the lanner falcons *(Falco biarmicus)*, used to be common migrants through the region. Through trapping, training, and hunting with migrant falcon species, the art of falconry using falcons became deeply entrenched in the desert way of life (Figure 55.2).

Current species widely used in falconry in the Middle East are discussed in the following sections.

Saker falcon

The saker falcon has been the favorite falcon among Arabs in the skillful art of falconry for centuries. Arab falconers have traditionally favored this species because of its remarkable endurance in flight, great strength, and the ability to cope with the rigorous environment of the deserts of the Arabian Peninsula. As stated earlier, the first person to train and hunt with falcons during the Al Jaheliya era was Al Harith bin Muawiyah bin Thor bin Kindah. This very first falcon was a saker falcon. Similarly, when Hamza bin Abdulmutallab bin Hashem embraced Islam after returning from a hunting trip, the falcon he was carrying on his wrist was also a saker falcon.[7]

The saker falcon is the largest of the desert falcons and the second largest falcon species in the world after the gyrfalcon *(Falco rusticolus)*. The color of the plumage is highly variable depending upon the geographical origin. Generally, the head is whitish to cream with dark-streaked feathers. The face is cream with dark brown eye stripe and moustachial streak. The throat and the nape are whitish to cream. In adult birds, the dorsal plumage or mantle ranges from pale brown and dark brown to almost black and very often with cream to pale brown tips. The ventral plumage is white cream to pale brown, heavily marked by dark brown streaks. The cere and feet are grayish yellow. In contrast, juvenile birds tend to have a darker plumage and the color of the cere and feet are gray-blue. The body weight of adult males is 730 to 950 g and that of adult females is 970 to 1300 g.[8]

Peregrine falcon

The peregrine falcon is without a doubt the "Prince of the Falcons." Its beauty, grace, and extraordinary speed are legendary among falconers from all around the world. In the Middle East, however, the peregrine falcon occupies only second place among the favorite species used in Arab falconry. The name in Arabic given to the peregrine is "Ash Shaheen," which is an expression derived from the Persian language meaning "balance." This is because the peregrine falcon cannot tolerate starvation or overfeeding. In some countries of the Middle East, falconers refer to peregrines as being "more fragile than glass."[7]

The peregrine falcon has the most extensive distribution of any of the largest falcons in the world. It is generally smaller than saker falcons, but with a strong, well-built, and stocky body. Peregrines have characteristically broad-based and long-pointed wings with relatively short tails. The head is black to dark slate gray-blue with white lower cheeks and throat. The face has a wide and well-defined black moustachial stripe. The color of the plumage varies according to the geographical origin. In adults, the color of the mantle ranges from dark gray and dark blue to black with a paler blue to dark blue rump. The ventral plumage is white to pale brown with small spots on the chest and the rest crossed with bars. The cere and feet are bright yellow-orange. In juvenile birds, the mantle is dark brown with paler feather fringes. The ventral plumage has dark brown streaks from the chest down to the lower abdomen. The cere and feet are gray-blue. The body weight of peregrine falcons varies considerably in the different subspecies, but in general, the body weight of females is 750 to 1300 g and of males is 582 to 750 g.[8]

Lanner falcon

The lanner falcon is a large desert falcon and yet another favorite species used in falconry in the Middle East. However, most experienced Arab falconers consider lanners as falcons for beginners as they lack the qualities of the ideal falcon to hunt large quarry such as houbara bustards *(Chlamydotis macqueenii)*.[7]

The lanner falcon is about the same size as a peregrine falcon, but with a slightly slimmer bodily configuration. The wings are longer and broader, with rounded wing tips and a longer tail. The color and markings of the head and nape vary according to the subspecies. The North African and Near East subspecies are creamy to pale brown, without streaks, with a dark brown forehead band and eye stripe; the southwest Arabian subspecies is more red-brown with dark brown streaks at the forehead; in the European subspecies, the lower part of the crown and nape is pale red-brown. The cheeks and lower forehead are white and with a long and narrow black moustachial stripe. The mantle is barred and brown-gray in color. The rump and the upper tail are slightly paler and barred. The ventral plumage is pale cream to white with small dark brown to black spots mainly around the flanks and thighs. The cere and the feet are yellow. Juveniles have darker streaked crowns, giving a "red-headed" appearance. The mantle and lower plumage are darker and heavily streaked. The cere and feet are gray-blue. The body weight of males is 500 to 600 g and females is 700 to 900 g.[8]

Gyrfalcon

The gyrfalcon is the largest falcon in the world and a species that is still highly valued in Arab falconry. Its large size and great strength made gyrfalcons very popular among Arab falconers during the early 1970s, but their popularity soon waned when it was realized that they were not able to cope with the extreme weather conditions prevalent in the Middle East.

The gyr is a large Arctic falcon, similar in appearance to a peregrine falcon, but heavier, greater in size, and with large broad-based pointed wings and tail. The color of the plumage varies according to the geographical origin, but three basic colors are recognized: white, gray, and black. In adult dark morphs, the forehead is white with a dusky eye patch and a weak moustachial streak. The upper plumage and mantle are gray-brown with a profusion of bars and notches. The ventral plumage is basically white, heavily marked by spots and thick bars on flanks and lower abdomen. In adult pale morphs, the plumage in general is white with sparse spots, bars, or streaks across the mantle, flanks, and thighs with dark brown to black primary wing tips. In the adult bird, the cere and feet are yellow. All markings in juvenile birds are brown rather than black and the ventral plumage is streaked instead of spotted. The feathers of the upper plumage and mantle have paler fringes. The cere and feet are gray-blue. The body weight of males is 805 to 1300 g and of females is 1400 to 2100 g.[8]

Hybrid falcons

A hybrid falcon is the product of a cross between two different species of falcons. This is achieved under captive conditions and by the use of artificial insemination (AI) techniques. The production of hybrid falcons was initiated during the early 1970s across the United States and Europe. Nowadays, hybrid falcons are produced mainly in Canada, United States, Germany, and the UK to supply the demand across the Middle East. The most common and popular hybrids are gyr-peregrines and gyr-sakers.[9] In Germany, hybrids with peregrine and saker have been prohibited since 2005.

Hybrid falcons came to replace the use of pure breeds in some countries, notably the UAE, after the Convention on International Trade of Endangered Species of Wild Fauna and Flora (CITES) legislation was reinforced in the country on April 26, 2003, and the import of wild-caught falcons was prohibited (Figure 55.3).[10]

Training

Balloons and kites

One of the early forms of modern training involved the use of balloons filled with helium and kites. Balloons and kites were sent about 300 to 400 m high using a thick fishing line (1.8 mm) fixed to a stake on the ground. A lure was suspended low from the ground (e.g., 10 m) using a second nylon fishing line (0.8 mm) and a falcon would be released to catch the lure. This was elevated gradually as the falcon approached, with the aid of a pulley fitted on the balloon or the kite, and using a battery-operated winch from the ground. The falcon was made to fly higher and higher gradually until it reached the lure and the falcon would bring it to the ground, where it was rewarded. The use of balloons and kites is now obsolete.

Fixed-winged remote-controlled airplanes

Inevitably, technological innovations of the 21st century have made their mark in the way falcons are trained today. Remote-controlled fixed-winged airplanes are now widely used for training falcons in all the countries of the Middle East where falconry is practiced. These are commercially available as petrol or battery operated. The bodies are built on a skeleton made up of lightweight plywood and balsa wood *(Ochroma pyramidale)* and covered by a hardened plastic film. Various sizes of airplanes fitted with engines ranging from 0.6, 0.8, 1.2, and 1.8 cc are used (Figure 55.4). These are the equivalent values of petrol engines. The airplanes are fitted with five servos: one for the rudder and one for the elevator of the tail, two for the ailerons of the wings, and one for the release

FIGURE 55.3 Several important steps have been taken in the Middle East to preserve falconry for future generations, including adhering to the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) and the creation of captive breeding programs to produce birds for hunting and racing and to stop relying in wild-caught falcons. Pictured here is one author's (M.P.J.) male gyrfalcon-peregrine falcon hybrid. (Photo courtesy Michael P. Jones.)

FIGURE 55.4 Fixed-wing remote-controlled operated aircraft are widely used nowadays in the training program of falcons destined for racing or hunting. This type of aircraft is commonly provided with two rechargeable batteries. One small battery is used to operate the servos of the rudder, the elevator of the tail, the ailerons of the wings, and the release mechanism, and a much larger battery to run the engine.

mechanism. The airplane carries one or two batteries depending on the size of the engine. These can maintain 5- to 8-minute flights at full throttle. An additional, much smaller, battery operates the servos. Each airplane is also fitted with a speed controller and a receiver. All the electric and electronic components of the airplane are operated by a transmitter or controller handled by an experienced operator from the ground. A train is made up using a 5-m nylon or cotton string, a lure, a parachute, and several swivels along the train to avoid entanglement. The train is fitted onto the release mechanism at the ventral body of the airplane. The training consists of allowing the falcon to chase the lure gradually at various speeds and heights and for a determined number of minutes. The falcon is then allowed to catch the lure at the end of the train; this is freed through the release mechanism by remote control, and the parachute slows the fall of the falcons. Training programs using fixed-winged aircraft include sessions for height, speed, and maneuverability. Falcons, or conversely, the airplane can be fitted with devices to read the height and the speed from the ground during flight.

The use of jet propulsion airplanes camouflaged as birds is popular in some countries in the West and by some individuals in the Middle East. However, these are mainly used in the Middle East for entertainment purposes rather than serious training as they never achieve the necessary speed to train a falcon.

Game launchers

Game launchers (Figure 55.5) are very popular in the training of retriever dogs but are also used by some parties for the training of falcons. Commercially available or purpose-built units are used. These consist of foldable arms lined with a band made up of canvas or plastic mesh and propelled by very strong springs. A prey, such as a partridge or a pheasant, is placed onto the band. The arms are then folded and held by a locking mechanism. This is operated through a single servo connected to a receiver fitted with an antenna so it can be operated at a distance of up to 400 m. A single battery operates the servo. When the locking mechanism is activated, the bird is propelled high into the air and begins to fly. The falcon

FIGURE 55.5 Game launchers are very popular in the training of retriever dogs but are also used for the training of falcons. These consist of foldable arms lined with a band made up of canvas or plastic mesh and propelled by very strong springs. A prey, in this case, a pheasant, is placed onto the band. The arms are then folded and held by a locking mechanism. This is operated through a single servo connected to a receiver fitted with an antenna so it can be operated at a distance of up to 400 m. A single battery operates the servo. When the locking mechanism is activated, the bird is propelled high up in the air and begins to fly. The falcon is then released to chase the live prey.

is then released to chase the live prey. It is common for game launchers to be placed within a pit in the ground. Therefore when the launcher is operated, the prey appears to fly out from the ground, simulating the natural escape flight of a bird flying from behind a bush.

Drones

Drones or multicopters are widely used for the training of falcons around the world and are very popular in the Middle East (Figure 55.6). Multicopters used in falconry are made up of a four- to six-arm lightweight frame carrying four to six engines fitted with propellers and speed controllers. A single large battery operates the engines, and they are fitted with a global positioning system (GPS) unit, a receiver, and servos. Multicopters need calibration in each geographic region of the world where they are used to identify the north magnetic pole. Hexacopters (six engines) are commonly fitted underneath with a box made up of aluminum or Perspex with a hatch with two doors as a floor. A live bird, such as a duck, partridge, or pheasant, is placed within the box through a loading door. The unit is sent up to the desired altitude and, through the servos, the hatch opens to release the prey. The falcon is then sent to pursue the prey. Conversely, quadcopters (four engines) are more commonly used to carry a lure and make the falcon chase it at a certain height and speed. This is particularly popular in the West.

Lures

The use of lures for the training of falcons is as old as falconry itself. In the Middle East, lures are made up using two wings or more of houbara bustard stitched together (Figures 55.7 and 55.8). A swivel is stitched in the carpal end of the wings. A nylon or cotton rope, 5 to 8 mm in diameter and

FIGURE 55.6 Drones or multicopters are widely used for the training of falcons in the Middle East. Hexacopters (six engines) are commonly provided with a single large battery to operate the engines and are fitted with a lightweight box with a hatch with two doors as a floor. A live bird, such as a pheasant, is placed within the box through a loading door. The unit is sent up to the desired altitude and, through the servos, the hatch opens to release the prey and the falcon is then sent to pursue the prey.

FIGURE 55.7 A fishing line is tied up to the jesses of a novice falcon before releasing it to a lure at the early stages of training. Fishing equipment can be placed to great use during training sessions replacing the much heavier cotton ropes widely used previously. This rope used for training is commonly called a "creance" in the Western falconry world.

approximately 1.25 m long, fixes the lure to a fishing rod. The lure is used in the same way in the East as in the West by calling and swinging the lure repeatedly to entice the falcon to come. When the falcon is close, the lure is moved swiftly, enticing the falcon to come back. This action is repeated each time the falcon dives. The distance and the number of passes are both increased gradually as the training advances.

Pigeons

Training falcons using live rock pigeons *(Columba livia)* is sadly still widely practiced in many countries in the Middle East. Commonly a pigeon is released and a falcon is sent to catch it. Pigeons are known to transmit several diseases to

FIGURE 55.8 Lure training is an essential part of the training program of any falcon or hawk used for racing or for hunting anywhere in the world. In the Middle East, a typical lure is made up of one or two pairs of houbara bustard *(Chlamydotis macqueenii)* wings tied up in a bundle. This is fixed to a short and thick fishing rod using a short 6- to 8-mm nylon rope.

falcons including trichomoniasis, inclusion body herpesvirus hepatitis, avian pox, and, notably, Newcastle disease. Collision accidents are very common when pigeons fly under cars with the falcon following at full speed and are unable to stop.

Hunting

Hunting is currently widely practiced in the Middle East and it is still enjoyed by a new generation of falconers. In the West, falconry is considered a sport, yet to Arab falconers, falconry is not a sport, but a way of life: an excuse to go back to the desert to sit with friends around a campfire and to reunite with a life that is already gone. Fast cars and fast-food restaurants in a fast-changing world have displaced customs and traditions, but falconry remains deeply rooted in the Arab cultural heritage as a way of communion with the past.

Modern Arab falconry hunting trips can be a small family affair, in which members of one or two families or a group of friends go out together for a few days. However, the hunting parties of members of the royal families can be a very large and complex concern lasting for up to 4 to 6 weeks and sometimes even longer. The size and complexity of these parties are directly related to who you are.

Falconry is still practiced in the Kingdom of Saudi Arabia. However, in countries such as Qatar, the Kingdom of Bahrain, Kuwait, and the UAE, falconry is almost nonexistent or extremely limited due to their territorial size. The Sultanate of Oman prohibited falconry and any form of hunting on its soil a long time ago.

The hunting method is simple. Generally, a group of six to eight falconers get into three to four cars or more and drive across the desert. Commonly, there is a leading car with a group of trackers walking in front, following the characteristic footprints of a houbara bustard impressed on the fine sand. When tracks are found, the trackers follow the trail until the houbara bustard flies and the falcon is released and the chase begins.

Technology from the 21st century has made a significant impact on traditional Arab falconry. In bygone days, Bedouins, on camelback, toiled for a full day to cover 30 to 45 km through the vast sands of the Arabian Peninsula in search of quarries. Today, falconers using four-wheel drive cars can cover the same distance in less than 1 hour. In days long ago, trackers used the position of the stars and planets, the signs left by the prevailing winds on the edges of the sand dunes, the marks left by the wind on the soft sand on the downwind side of a clump of grass, and the charred signs left by the fierce sun on trees and bushes in order to find their way around the desert. Nowadays, trackers can use a compass for orientation or make full use of conventional GPS technology to accurately pinpoint a particular spot in the desert or to navigate through an endless sea of sand dunes using GPS coordinates to mark the trajectory. In the old days, falconers lost many falcons flying beyond the horizon during a persistent chase of a bustard. Now, telemetry technology can track a falcon as far as 30 to 40 km away.

However, in spite of the technological innovations, falconry in the Arabian Peninsula is still as traditional as the falconers themselves. What has been described before are commodities of life, which have had the same effect in the East as in the West, but it has little or nothing to do with falconry itself.

Falcons in the Middle East are still selected and valued by the measurement of the total length from the shoulder to the tip of the tail, the girth around the shoulders, and the color of the plumage. Falcons are still fitted with the same type of falconry furniture, following the same pattern as the one designed in ancient times. Falconers still train falcons using a lure made of bustard wings tied up in a bundle as was done by their forefathers. The favorite quarry is still the elusive and well-camouflaged houbara bustard.[11–14]

Racing

With the advent of laws and legislation regulating hunting in each country and the inability of falconers to hunt in neighboring countries such as Pakistan, many falconers have turned to falcon racing as a pastime and to continue flying falcons. Falcon races are nothing new. These were discussed 30 years ago as a possibility, but plans never took off the ground until recently. Nowadays, racing is a sport widely practiced in every country in the Middle East where falconry is allowed. The races consist of allowing a falconer to release the falcon from the wrist to a calling falconer swinging a lure at a distance of 400 m. The falcon has to fly low. The winner is the falcon that is able to fly the same distance in the shortest possible time. Several categories are made using pure species and hybrids, males and females, and age.

To prove how popular falcon racing has become in the Middle East in recent years, in February 2019 the King Abdulaziz Falconry Festival in the Kingdom of Saudi Arabia was declared the world's largest falcon racing tournament ever with participation of a record 1723 falcons competing over a 10-day (January 25–February 3) period, winning a place in the *Guinness Book of Records*. The total cash prize was SR 17,630,000 (US $4,700,691.48), with the participation of falconers from the Kingdom of Saudi Arabia and other countries in the Middle East and the rest of the world.

Quarry

Houbara bustard

The houbara bustard has been the favorite quarry of Arab falconers for centuries (Figure 55.9). Its enduring strength in flight, the exquisite camouflage of its plumage that allows it to blend with its surroundings, and the diverse array of devices at its disposal to defeat the falcon are legendary among falconers in the Middle East.[7]

The houbara bustard is a medium-sized desert bird inhabiting steppes, harsh open plains, and scrub desert. There are three different subspecies of houbara bustard: the North African *(Chlamydotis undulata undulata)*, from North Mauritania to Egypt; the Canary Island *(Chlamydotis undulata fuertaventurae)*, from the Eastern Canary Isles; and the Asian species the MacQueen's bustard *(Chlamydotis macqueenii)* from the Sinai and Arabian Peninsulas, and North Caspian Sea east to Baluchistan, Afghanistan, Kazakhstan, and Mongolia. The Canary Islands and North African subspecies are virtually sedentary, while the Asian subspecies migrate from Central Asia in the autumn, southwest, wintering mainly in Pakistan, northwest India, Iran, Iraq, and the Arabian Peninsula. Houbara bustards are opportunistic omnivores, feeding on invertebrates, such as beetles and ants; plant material including leaves, flowers, and fruits; and small vertebrates, such as geckos and skinks.[15]

Asian subspecies adult males weigh 1.5 kg to 2.4 kg, and adult females 1.1 kg to 1.7 kg. The breeding season varies according to the latitude of its habitat. In the northern part of its range (Kazakhstan, Mongolia), the breeding season is between April and June, while in southern areas (Balochistan, Afghanistan), it is between March and May. The female usually lays two to four eggs. Only the female incubates the eggs, and the chicks hatch after a period of around 23 days. The chicks fledge after a period of 32 to 38 days.[15]

FIGURE 55.9 The houbara bustard *(Chlamydotis macqueenii)* has been the favorite quarry of Arab falconers for centuries. Its enduring strength in flight, the exquisite camouflage of its plumage that allows it to blend with its surroundings, and the diverse array of devices at its disposal to defeat the falcon are legendary among falconers in the Middle East. Captive breeding programs have been established in the Middle East since the mid-1980s to release captive-bred stock back into the wild and thus ensure the survival of the species for future generations.

Although the MacQueen's bustard has a wide distribution, its number has been steadily declining due to overgrazing, intensive farming, pesticides, and hunting in the countries where it breeds and by urban development, unregulated hunting, and trapping in the countries through which it migrates.

Several conservation projects were established in the Middle East as early as the late 1980s to preserve and increase the houbara bustard by captive breeding and release and habitat protection and restoration.[16]

Cape hare

The Cape hare *(Lepus capensis)* has been a favorite prey of Arab falconry for centuries. Yet the hunting of hares is regarded as a delicacy among Arab falconers since it requires highly selected falcons specially trained for that purpose.

The Cape or desert hare is a medium-sized mammal that inhabits open scrub desert and submountainous regions across the Middle East. In the Middle East, the color of its coat varies according to the time of the year. During the summer, the coat is sandy-brown in color, while during the winter, the color is grayish-brown. Hares have large ears, which act as radiators through a mechanism called thermoregulation. The ears have a vast network of blood vessels through which the circulating blood is cooled down before returning to the body. When threatened, hares have the tendency to "freeze," blending perfectly well with the surrounding habitat. Its cryptic coat also contributes to a near-perfect camouflage. It is possible for a crouching hare hiding behind a bush to go completely unnoticed by a passerby walking beside it.

Hares are more active during the early hours of the morning and late afternoon. It is mainly during the evenings that the desert hare feeds. Its diet includes leaves, grasses, and roots. Hares do not dig burrows and prefer to shelter within a thick grass patch or under a dense bush. Hares breed throughout the year giving birth to up to four litters. Each litter consists of up to four young.[17]

Stone curlew

The stone curlew *(Burhinus oedicnemus)* is also a favorite quarry among Arab falconers. Its small size makes it ideal for beginners carrying smaller falcons such as lanner falcons, or male saker, and male peregrine falcons.

The stone curlew is a medium-sized terrestrial bird inhabiting Mediterranean, steppe, mild temperate, and arid zones. There are six subspecies of stone curlew: *B. oedicnemus oedicnemus*, found across Europe, from southern England to southern Russia, and south to Siberia, Italy, the Balkans, and Caucasus; *B. oedicnemus saharae*, found on the Mediterranean Islands, Greece, Turkey, and southwest Iran, and south to North Africa; *B. oedicnemus harteri*, found in southeast Russia and central Iran, east through Kyrgysztan and Kazakhstan to the Zaisan basin; *B. oedicnemus insularum*, found on the eastern Canary Islands; *B. oedicnemus distinctus*, found on the western Canary Islands; and *B. oedicnemus indicus*, found in India and Sri Lanka to Southeast Asia. The stone curlew is not a resident species in the Arabian Peninsula, appearing only during its winter migration. It is believed that the subspecies that migrate through the Middle East are *B. oedicnemus saharae* and *B. oedicnemus harteri*.[15]

Stone curlews feed mainly at night on invertebrates such as beetles, ants, grasshoppers and crickets, flies, moth caterpillars, earthworms, and small vertebrates such as lizards, amphibians,

and mice. Adult males weigh 450 to 475 g, while females weigh 415 to 440 g. The breeding season in most of its range is from February to early June.

The female lays from one to three eggs and the chicks hatch after an incubation period of 24 to 26 days. The chicks fledge between 36 and 42 days.[15]

There are no formal conservation programs specifically devoted to hares or stone curlews in the Middle East, but the hunting of houbara bustards, hares, and stone curlews is prohibited or regulated by law in the countries of the region.

FALCONRY IN THE MIDDLE EAST—THE FUTURE

As stated previously, falconry forms an integral part of the Arab cultural heritage. As a tradition, falconry has defied time and adversity and it will continue to be part of life in the Middle East. Falcon races came to fill a vacuum left by the inability of ordinary falconers to use falcons for hunting and are attracting hundreds of falconers from different countries in the Middle East tempted by the lucrative prizes. Hunting is almost exclusively reserved for individuals of the royal families or wealthy individuals with the necessary resources to hunt in their own country or to travel abroad. Pakistan is still a very popular destination for hunters, but it is becoming more difficult to obtain the necessary permits and licenses to hunt in the country. After the collapse of the Soviet Union on December 26, 1991, some of the newly created countries, such as Kazakhstan, Azerbaijan, Uzbekistan, and Kyrgyzstan, opened the doors to selected groups of Arab hunters to hunt in some areas of their territories. This practice has continued to date. However, this practice has placed an immense pressure on the free-living population of the Asian houbara bustard as these are among some of the countries in which the species breeds.

Only by joining forces, pooling resources together, and adequate legislation could it be possible to tell if the Asian houbara bustard will continue to flourish protected in their breeding grounds and in the range of countries through which they migrate and to continue with captive breeding and release programs to ensure the survival of the species.

The mystical relationship between falcons, Arab falconers, and the houbara bustard has defied time as the tradition continues almost unchanged by time, technological advances, and commodities of the 21st century.

FALCONRY IN ASIA—THE PAST

Asia is the largest and most densely populated continent in the world covering an area of 44,579,000 km^2 (17,212,000 square miles), representing about 30% of the total land area and 8.7% of the total surface area of planet Earth. The continent is home to 4.5 billion people (June 2019) comprising approximately 60% of the total population of the world. The Asian continent is subdivided into five geographical regions, including the following countries: Central Asia (Tajikistan, Uzbekistan, Kazakhstan, Turkmenistan, and Kyrgyzstan); East Asia (China, Mongolia, North Korea, South Korea, Japan, Hong Kong, Taiwan, and Macau); South Asia (Sri Lanka, Bangladesh, India, Afghanistan, Pakistan, Bhutan, Nepal, and the Maldives); Southeast Asia (Brunei, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, Timor Lester, Vietnam, Christmas Island, and Cocos Islands); and Western Asia (Georgia, Armenia, Azerbaijan, Turkey, Cyprus, Syria, Lebanon, Israel, Palestine, Jordan, Iraq, Iran, Kuwait, Bahrain, Qatar, Saudi Arabia, UAE, Oman, and Yemen).[18]

Some of the earliest archaeological findings on falconry are from Mesopotamia, a large area corresponding to present Iraq, Kuwait, eastern Syria, southeastern Turkey, and regions along the Turkish-Syrian and Iran-Iraq borders in Western Asia. Some of the earliest evidence of falconry can be seen in several carvings from archaeological sites in the ancient Neolithic and Hittite city of Alaca Höyük, situated in Alaca, Corum Province, in north-central Turkey and in Karatepe, a late Hittite fortress in Osmaniye Province, southern Turkey, dating 1400 to 1600 BCE. In one such carving, a large bird can be seen on the fist of a human figure holding a hare from its hind legs. In another example, a bas-relief found in the ruins of Khorsabad of the palace of the Assyrian King Sargon II in present northern Iraq, dated 722 to 705 BCE, shows a man with a small bird of prey on his fist. This image depicts the bird fitted with jesses passing between the thumb and forefinger of the holder. This is clear evidence that falconry and the use of falconry furniture was already in use in the eighth century BCE in Mesopotamia. These archaeological carvings and bas-reliefs depicting human figures carrying birds of prey fitted with falconry furniture suggest that falconry is at least 3500 years old in Mesopotamia.[19–23]

In the Korean peninsula, falconry arrived c. 220 BCE and was entangled with military and political affairs. In China, falconry also played a very important role in politics. Written records go back to 700 BCE depicting falconry as it is practiced today. The imperial time of the Chu Kingdom used falcons, eagles, and shortwings as widely used in modern falconry. This would place the beginning of falconry in the region at over 3000 years.[24]

Archaeological excavations throughout Western Asia, but particularly in Palestine, Israel, Jordan, Syria, Iraq, and Iran, in recent times are shedding new information on the possible use of birds of prey for hunting, dating back 8000 to 10,000 BCE. This evidence is in the form of bone remains found at archaeology excavations. This has been investigated by scientists from a branch of archaeology denominated zooarchaeology, the branch responsible for the study of bone remains primarily from mammals and birds found at archaeology sites. Many of the bones recovered have been identified as bones from birds of prey. Some scientists consider that these findings are remnants of food left by the inhabitants of the settlements, but the bones might actually represent the earliest evidence of training and hunting with birds of prey. Aside from bird of prey remains, these archaeological sites also harbored bone remains of prey species matching the range of prey species of current birds of prey, including gazelles (*Gazella* spp.), foxes, (*Vulpes* spp.), hares (*Lepus* spp.), partridges, francolins, and sandgrouse. Could this indicate that birds of prey were used by inhabitants of these settlements to hunt the smaller species, throwing the origin of falconry into the late Stone Age?[23]

Takagari was the art of hunting with trained goshawks, eagles, and falcons in Japanese. Due to the great cost and the time required to train and maintain the birds, it was only available to the nobility and became symbolic of their status and spirit. The sport of the samurai elite. Takagari was referred to

in the *Kojiki*, the Records of Ancient Matters, written in CE 712, the *Nihon Shoki*, the Chronicles of Japan, dated CE 720, the anthology of poems known as the *Manyoshu* from CE 759, as well as the *Genji Monogatari*, Tale of Genji. Records indicate that falconry in Japan started in the fourth century. According to writings in the *Nihon Shoki* (CE 720), falconry was first introduced by the Baekje noble Sakenokimi in CE 359 during the reign of Emperor Nintoku, the legendary emperor of the fifth century. The Japanese Emperor Saga (CE 786–842) was the 52nd emperor of Japan, reigning from CE 809 through 823. In CE 818, the emperor ordered the editing of the first surviving textbook on falconry named *Shinshuu Youkyou*.[25,26]

Maharaja Suraj Mal (CE 1707–1763) or Sujan Singh was a Hindu Jat ruler of Bharatpur Rajasthan, India. He was well known for his political knowledge, steady intellect, and clear vision. He was one of the greatest warriors and ablest statesmen ever born in India. His audacity proved a fierce foe to the Moghuls when they tried to capture Bharatpur in vain. There are ancient paintings depicting the Maharaja together with a goshawk, suggesting his interest in falconry, as with many of the Maharajas in the subcontinent at the time.[27,28]

Drawings of the Sambal tribes in the Philippines recorded in the *Boxer Codex* showed the practice of falconry. The *Boxer Codex* or *Manila Manuscript* is a manuscript written around the 1590s, containing illustrations of ethnic groups in the Philippines, ethnic groups across Southeast Asia, East Asia, and Micronesia at the time of their initial contact with the Spanish conquistadores with additional Taoist mythological deities and demons, and both real and mythological birds and animals copied from popular Chinese texts and books in circulation at the time. The Sambal people are one of the smallest of the Filipino Muslim ethnic groups. They originally came from the Island of Sangihe in Indonesia.[29]

The *Baz-Nama-Yi Nasiri* is an early treatise on Persian falconry compiled by Taymur Mirza. This is a 19th-century manual on the art and sport of hunting with birds of prey. Taymur Mirza was a member of the Qajar dynasty (CE 1785–1925) and grandson of Fath Ali Shah, Shah of Iran. The book classifies the birds used in falconry into two traditional taxonomies: "dark-eyed birds" and "yellow-eyed birds." Examples in the first category are eagles and buzzards, and in the second, various hawks, owls, and osprey. In the book, Taymur Mirza covers the husbandry of raptors, their capture, training, diet, and treatment of diseases, illustrated with examples from his own experience. It has been documented that the first personage to use birds of prey for hunting in the region was Tahmures, the son of Hushang, the third Shah of the Pishdadian dynasty of Persia, placing the birth of falconry in the region to 8000 years to 10,000 years BCE.[19–23]

Moamyn (or Moamin) was the name given in Medieval Europe to an Arabic author of a five-chapter treatise on falconry, important for early Europeans, which was most popular as translated by the Syriac Theodore of Antioch under the title *De Scientia Venandi per Aves* in common era (CE) 1240 to 1241. The treatise also contained a chapter on hunting with dogs and chapters on other related subjects such as diseases of birds. There are about 27 Latin manuscript versions of the work of Moamyn, with two versions highly illustrated throughout. The work of Moamyn is largely based on the *Kitāb al-ṭuyūr*, the Book of Birds or *Kitāb Dawari At-Tayr*, the Book of Flight Cycles (patterns) of Birds, a more extensive work by al-Ghiṭrīf ibn Qudāmah al-Ghassānī from the early ninth century.[7]

The Oghuz, Oguz, or Ghuzz Turks were western Turkic people who spoke the Oghuz languages from the Common branch of the Turkic language family. In the eighth century, they formed a tribal confederation conventionally named the Oghuz Yabgu State in Central Asia. The Oghuz, forefathers of the Turkmen people who lived 5000 years ago, had falconry symbols on the ancestral emblems, carpets, pottery, and in other archaeological findings.[19–23]

FALCONRY IN ASIA—THE PRESENT

Birds of Prey Species Used in Falconry in Asia

Eagles have played a predominant role in the traditional way falconry was practiced by the Kazakhs and Kyrgyz, in modern Kazakhstan and Kyrgyzstan across the steppes of Central Asia, and diasporas in Bayan-Ölgii Province, the west of Mongolia, and Xinjiang Province in northwest China. The most common species used in falconry were the golden eagle *(Aquila chrysaetos)* and the Eurasian goshawk.

There appears to be a great deal of controversy on the etymology of the name bāz as a favorite bird of prey used in falconry in Persian falconry. The definition of bāz in early Persian texts does not allow identification of the species as these refer vaguely to "well-known predatory or hunting species" or "a well-known species widely used by Kings and Dignitaries for hunting." In the Middle Ages, however, the name bāz was distinguished from other species such as the bāsa or sparrowhawk *(Accipiter nisus)*, the šāhān or Barbary falcon *(Falco pelegrinoides)*, or peregrine falcon according to the different authors, the čarğ/čark or saker falcon and the oqāb, traditionally accepted to be the eagle. More precise information on the bāz was provided in the *Nowrūz-nāma*, attributed to the philosopher and mathematician Omar Ḳayyām (first quarter of the 6th to 12th century). "The bāz is of numerous kinds, but the best is the white one and those with plain red or plain yellow plumage. The white one is the greediest for hunting, but it is prone to disease and ill-tempered; the yellow one is both greedy and healthy; the red one is larger and healthier than the other two kinds, but it is ill-tempered." It is now widely accepted that the bāz, as described by early Persian textbooks, corresponds to the Eurasian goshawk.[19–23]

Golden eagle

The golden eagle (Figure 55.10) is a large bird of prey measuring 66 to 102 cm in length and with a wingspan of 1.8 to 2.34 m. The wingspan of golden eagles is the fifth largest among living eagle species. Females are larger than males. In adult birds, males and females have similar plumage and are primarily dark brown, with some gray on the ventral aspect of the wings and tail and a paler golden color on the back of the crown and nape. The Asian golden eagle, Himalayan golden eagle or berkut *(Aquila chrysaetos daphanea)*, is believed to be the most commonly used in the region for falconry. This subspecies is distributed in central Kazakhstan, eastern Iran, and the easternmost Caucasus, distributed to Manchuria and central China and along the Himalayas from northern Pakistan to Bhutan and discontinuing in northeastern Myanmar (rarely ranging over into northernmost India). This subspecies is the

FIGURE 55.10 Golden eagles *(Aquila chrysaetos)* have been used for hunting in Central Asia for centuries. The quarry is mainly the Mongolian wolf *(Canis lupus chanco)* and steppe wolf *(Canis lupus campestris)*, but the tolai hare *(Lepus tolai)* is also hunted to a lesser extent. The Asian golden eagle, also called Himalayan golden eagle or berkut *(Aquila chrysaetos daphanea)*, is believed to be the most commonly used species for falconry in the region. (Photo courtesy Javier Ceballos.)

largest among all the subspecies. Males weigh 4.05 kg, while females weigh 6.35 kg on average.[8]

Eurasian goshawk

The Eurasian goshawk is a medium- to large-sized bird of prey (Figure 55.11). The scientific name in Latin, *Accipiter*, means to receive, and *gentilis* means noble or gentle, since in the Middle Ages, only the nobility was allowed to use goshawks for falconry. The Eurasian goshawk is found across most of Russia, with the exception of the tundra in the northern ranges, to the western limits of Siberia as far as Anadyr and Kamchatka peninsula. There are 9 to 10 subspecies of the Eurasian goshawks described throughout its range. The pale forms are from the boreal zones of the Palearctic. The plumage of the subspecies *A. g. albidus* is polymorphic but generally creamy to white in color. Male of this species are 46 to 61 cm in length and with a wingspan of 89 to 105 cm. The female is much larger, 58 to 69 cm in length, with a wingspan of 108 to 127 cm.[8]

Hunting

In the Kazakh and Kyrgyz languages, there are distinct names for those hunting with eagles and those hunting with other birds of prey. The Kazakh word for falconers who hunt with eagles is "búrkitshy," from "búrkit" (golden eagle), while the name for those who hunt using goshawks is "qarshyghashy," from "qarshygha" (goshawk). In Kyrgyz, the general word for falconers is "münüshkör." A falconer who specifically hunts with eagles is a "bürkütchü," from "bürküt" (golden eagle).

During the communist period, many Kazakhs fled to Mongolia, settling in Bayan-Ölgii Province and bringing with them their tradition of hunting with eagles. There are an estimated 250 eagle hunters in Bayan-Ölgii, which is located in the Altai Mountains of western Mongolia. Their falconry custom involves hunting with golden eagles on horseback, and they primarily hunt red foxes *(Vulpes vulpes)* and corsac foxes

FIGURE 55.11 The use of the Eurasian goshawk *(Accipiter gentilis)* in falconry was very popular in many East Asian countries such as India and Pakistan and in some Middle Eastern countries, notably in Iran. It is now widely accepted that the name "bāz," as described by early Persian textbooks, correspond to the Eurasian goshawk. (Photo courtesy Javier Ceballos.)

(Vulpes corsac). They use eagles to hunt foxes and hares during the cold winter months when it is easier to see the gold-colored foxes against the snow. Each October, Kazakh eagle-hunting customs are displayed at the annual Golden Eagle Festival. Although the Kazakh government has made efforts to lure the practitioners of these Kazakh traditions back to Kazakhstan, most Kazakhs have remained in Mongolia. In Turkmenistan the art of falconry differs from those in the neighboring traditions of using eagles. The practice of falconry in Turkmenistan is similar to the traditional falconry of Iran, Afghanistan, and some countries of the region, using saker falcons and tazy (saluki).[23,30]

In Pakistan, falconry is still practiced but is rapidly declining, with only a small number of falconers remaining in Punjab, Sindh, Balochistan, and Khyber Pakhtunkhwa, formerly known as the North-West Frontier Province. The different birds of prey used in falconry in Pakistan can be divided into birds with red eyes including the shikra *(Accipiter badius)*, sparrowhawk, and goshawk and birds with black eyes including peregrine, saker, and luggar falcons and merlin *(Falco columbarius)*.[31]

In present-day Turkey and Georgia, falconers are only allowed to hunt using sparrowhawks. In Turkey, there are just over 4,000 registered falconers, while in Georgia there are only just over 500 falconers. Georgia was the first state of the former Soviet Union to legalize falconry in 1967.

FALCONRY IN ASIA—THE FUTURE

The decline of the Ottoman Empire marked the decline of falconry in the Middle East, Eastern Europe, and North

Africa. The Ottoman Empire was one of the most powerful and longest-lasting dynasties in world history. Under a treaty agreement, most Ottoman territories were divided between Britain, France, Greece, and Russia. The Ottoman Empire officially ended in 1922 when the title of Ottoman Sultan was eliminated.

To the knowledge of the authors, falconry is banned in India, Jordan, Israel, and Oman. However, in most countries of Asia, falconry is still practiced and enjoyed by a new generation. In many countries of the region, falconry is organized under falconry clubs. However, it is firmly believed that falconry will continue flourishing in the different nations of the Asian region as part of the cultural heritage for future generations.

In 2010, UNESCO declared falconry a living human heritage element of 11 countries, including the UAE, Belgium, Czech Republic, France, Republic of Korea, Mongolia, Morocco, Qatar, Saudi Arabia, Spain, and Syrian Arab Republic. Austria and Hungary were added in 2012, and Germany, Italy, Kazakhstan, Pakistan, and Portugal were added in 2016. With a total of 18 countries, falconry is the largest multinational nomination on the Representative List of the Intangible Cultural Heritage of Humanity.

FALCONRY IN AUSTRALIA

In Australia, all Falconiformes and Strigiformes are protected under regional legislative acts and regulations. As such, it is illegal in all states and territories to kill, injure, take from the wild, hold captive, trade, or band any raptor without a permit issued by the relevant government authority. Permits are mostly granted for scientific, artistic, exhibition, or rehabilitation purposes, or—in rare instances—to scare, remove, or destroy raptors causing an economic nuisance or causing a threat to human safety (e.g., at airports). While the State of Victoria retains a right for citizens to apply for a falconry permit, in practice, such permits are never granted, and falconry is effectively prohibited throughout the country. Any offenses involving a raptor may lead to substantial fines of up to AU $10,0000 or up to 6 months imprisonment.[32]

FALCONRY IN EUROPE—THE PAST

A day without falconry is a wasted day.
Emperor Frederick II (CE 1194–1250)

First reports about a collaboration between men and birds of prey in Europe were given by Aristotle in antiquity, around 350 BCE, who described fowling in the marshes of Thrace with the aid of raptors.[33] He, and later Pliny, reported on men using sticks to put up little birds from bushes and reeds and falcons soaring above them to drive these birds down to the ground. In these descriptions, the fowlers caught the birds using nets and sticks and shared their prey with the falcons in a kind of hunting partnership.[33,34] However, there are no detailed descriptions of human beings training and keeping raptors for falconry until CE fourth to fifth century. Falconry was brought to Europe from Asia by migrating Gothic tribes and the nomadic Khazars of the northern Caucasus. It expanded westernmost during the reigns of the Visigoth kings Alaric I (CE 370–410), Theodoric I (CE 390–451), and Euric (CE 440–484).[34] In those days, falconry was common and practiced by large parts of the populace as an efficient way of hunting to catch nourishment for human consumption. This has been documented by the author Paulinus of Pella (CE 376–459) in his autobiographical poem entitled "Eucharisticos" (Greek for "Thanksgiving").[34] Likewise, the French bishop Sidonius Apollinaris described Emperor Avitus (CE 385–457) practicing falconry and implementing it as part of the education of young gentlemen, for it was thought to prevent illness and to demand the cultivation of personal qualities such as skill, education, and patience.[6] Besides written evidence, early pictorial testimonials of falconry were found in different parts of Europe. In the south, at Argos in Greece, a floor mosaic in the Roman "Villa of the Falconer" representing a falconry scene dates back to CE 500.[33] In Georgia and the Republic of Tuva, stone sculptures from the CE fifth and sixth centuries represent early evidences of falconry in the east.[34] In European literature of these centuries falconry has been mentioned in CE 627 to 630 by Archbishop Isidore of Seville (CE 560–636), who included a description of a falcon perching on a falconer's hand in his work *Etymologiae* (Latin for "the etymologies" or "the origins").[34]

Gradually falconry in Europe transformed from a popular way of hunting for everybody to a privilege of nobility, clergy, and people of a certain social status. Thus birds of prey were included into the Salic Law (CE fifth century), the Burgundian Law, and the Ripuarian Law (CE sixth century), and the larceny of falconry birds was punished.[33,34] In particular, the Burgundian Law covenanted that the thief of a hunting bird should get 6 ounces of flesh torn from his breast by the raptor he had stolen.[33,35] In contrast to commonality, emperors, kings, princes, and high officials of the church did not practice falconry for sustenance but for pastimes, competition, and sport. Hence, at the royal courts of Europe the quarry transformed subsequently from partridges *(Perdix perdix)* and other animals for gourmet cuisine to grey herons *(Ardea cinerea)*, common cranes *(Grus grus)*, carrion crows *(Corvus corone)*, red kites *(Milvus milvus)*, and black kites *(Milvus migrans)*, offering more spectacular and prestigious hunting events. In the ninth century in some regions privileges of aristocracy were expanded beyond death, when it was set as the right and honor of a gentleman to keep his sword and his goshawk after falling in a battle.[34] Physicians such as the magister Ububchasim de Baldach from Baghdad, who wrote the Arab medical treatise *Theatrum sanitatis* (Latin for "theater of health"), recommended in the 11th century to practice hunting and falconry in order to maintain health and fitness. At the same time, falconry should offer the greatest amount of pleasure and allow man to live in harmony with nature.[34]

Among the European monarchs, the Hohenstaufen dynasty became famous for their dedication to falconry. In the 12th century, Emperor Barbarossa (Frederick I; CE 1122–1190) was the first of the Hohenstaufen who practiced falconry by training dogs, horses, and numerous falcons. This passion was adopted by his son Emperor Henry VI (CE 1165–1167). However, the grandson of Barbarossa, Emperor Frederick II of Hohenstaufen (CE 1194–1250), should become famous as the greatest falconer of his age.[33,34] Growing up in Sicily, he was fascinated by nature, life sciences, and ornithology and appreciated the lanner falcon as his favorite bird of prey species of his home region. It is recorded that he

practiced falconry as often as possible, besides royal duties and even on the battlefield. He enjoyed hunting cranes with gyrfalcons and herons with peregrine falcons and employed Arab, German, Spanish, and English falconers at his court.[6,36] Frederick II is alleged to have said that a day without falconry should be considered to be a wasted day.[34] Following this maxim, he managed to achieve the writing of a vast and extraordinary treatise about hunting with birds of prey, published under the original title *De arte venandi cum avibus* (Latin for "from the art of hunting with birds").[33] For this purpose, he consulted falconers all around the globe to exchange experiences in order to distill the knowledge, techniques, and technologies of falconry of different cultures and geographic regions. Being able to speak nine languages including Arabic, he was able to communicate with falconers from the Middle East. Thereby he discovered the hood for falcons during a Crusade to Jerusalem (CE 1228–1230).[34] This literary oeuvre took him nearly 30 years until CE 1247 and still is a milestone in falconry literature. In total, more than 140 treatises were written in medieval Europe about falconry between the 10th and 16th centuries in Latin, Italian, Portuguese, Spanish, Catalan, Dutch, German, French, and Occitan, all offering a variety of experiences, techniques, and practical tips.[34] For example, in France falconry has been documented by Charles D'Arcussia in *La fauconnerie* (French for "the falconry") (CE 1589) and in Portugal by Diogo Fernandes Ferreira in *Arte da caça de altanería* (Portuguese for "the hunting art of falconry") (CE 1616).[34]

The demand and value of raptors increased from the early Middle Ages to the Renaissance. Birds of prey, and first of all falcons, were caught from the wild during their migration on the main passage route in Flanders, Belgium, and the Netherlands.[34,35] The small Dutch town Valkenswaard in Brabant (Dutch for "wait or look out for falcons") is a still existing testimony of the involvement of professionals and entire families in service of the courts, handing down the skills of catching falcons from generation to generation. Likewise, the monarchs of northern European countries, especially the king of Denmark, who was also for a long time ruler of Norway and Iceland, caught fledged gyrfalcons and goshawks or took them from nests and distributed them by traders across the continent.[33] They were regarded as desirable gifts between kings and princes, able to solve political discrepancies or to consolidate liaisons. Thus more than 50 different courts received these special presents. For example, in CE 1764 it is recorded that a total number of 162 falcons went to the French King ($n = 50$), the German Emperor ($n = 30$), the King of Portugal ($n = 60$), the Landgrave of Hesse ($n = 20$), and to the French Ambassador ($n = 2$). Besides European sources, European conquistadors requested exotic raptors from regions in the New World after the discovery and colonization of the Americas. Thus in CE 1492 Christopher Columbus was requested by the monarchs to send as many exotic falcons as possible to the Spanish court, and likewise, Hernán Cortés (CE 1485–1547), the Councilor of the Indies, agreed to send annually 50 hunting birds to continental Europe.[34] He had witnessed in Mexico that Aztec King Montezuma previously kept and maintained a large collection of raptors, possibly used for hunting (see also section on Falconry in Mexico), although this is debatable.[33] Another example of the high value as a diplomatic gift is the granting to nobles of the island of Malta and Tunisia by Charles the V of Germany in return for giving him one white gyrfalcon.[35] Falconry with its symbolic system was shared between most cultures and its geographical reach was extraordinary in the 17th century. Falcon trading ranged from France to Russia, from Norway to Sicily, toward Corsica, Sardinia, Balearic Islands, and across Turkey back to Asia and North Africa.

Louis XIII the Just (CE 1601–1643), King of France and Navarre, who became king shortly before his ninth birthday, seemed to be more interested in falconry than in political business and spent large amounts of time and money for this noble sport.[34] His falconry consisted of 300 birds, subdivided into six specialized equipages for hunting herons, kites, crows, waterfowl, and partridges.[6] In Germany, the Margrave Charles William Frederick of Brandenburg-Ansbach (CE 1712–1757) was one of the well-known and dedicated falconers of the 18th century. He ruled as a typical absolute monarch with a luxurious court life and extensive hunting and falconry, which earned him his nickname, the Wild Margrave. He spent at least 10% of the annual national budget on falconry, employing 43 falconers divided into heron, kite, crow, and rook hawking groups.[36] It is reported that 35,000 creatures were hunted by him and his entourage within 20 years. Additionally, Clemens August of Bavaria (CE 1700–1761), member of the Wittelsbach dynasty of Bavaria and Archbishop-elector of Cologne, assiduously practiced falconry and patronized the arts.[34] In this regard, he ordered the building of the extraordinary and quixotic palaces of Augustusburg and Falkenlust (German translation of "passion for falcons") in Brühl, North Rhine-Westphalia, both listed on the UNESCO cultural world heritage list as significant artistic representations of falconry and hunting.[34]

Two main factors led to a rapid cessation of falconry in Central Europe in the late 18th century. Firstly, the French Revolution (1789) and the associated social changes during the Age of Enlightenment/Reason led to the rejection and prohibition of everything that has been associated with the aristocracy.[34] Additionally, the development, optimization, and increased availability of firearms made raptors as hunting partners superfluous. In contrast, in these times, goshawks and other birds of prey were regarded as competitors and became victims of human hunting. Thus falconry almost faded away in the early 19th century in the entire continental Europe,[35] except a shortly expanded preservation in Holland under the patronage of Prince Alexander. There, the creation of the short-lived Loo Hawking Club (1839–1855) enabled falconers from England and Holland to join high flights in the heath around to the Palace of Het Loo in Apeldoorn until the end of the 19th century.[34]

At that time, hunting law in Germany changed fundamentally, as after the failure of the German revolution in the spring of 1848, hunting was no longer regarded as regalian right but linked to property instead. Thus in the 19th century hunting became legal for all citizens owning a certain minimum area of a hunting district.[37] Extensive, crude, and unsustainable forms of hunting broke through, calling for the implementation of a hunting code of ethics, and hence, for consideration of the notion of animal protection. In these discussions, falconry was regarded as a particularly ethical and fair method of hunting, being not focused on large hunting bags and financial revenues.[37] To "reanimate" the idea of falconry, exchanges with falconers from Great Britain and

Ireland during the First International Hunting Exhibition in Kleve in 1881 and later for various presentations in eastern Germany during the autumn of 1904 were important stimuli.[37] Some years later in 1921 the German Falcon Order (Deutscher Falkenorden [DFO]) was formed in Berlin as the first falconer association in Europe, being still the oldest and one of the largest falconer associations in the world.[6] This foundation was made by people such as the physician Dr. Friedrich Jungklaus (1875–1953), the art student Renz Waller (1895–1979), Dr. Fritz Engelmann (1874–1935), Dr. Hermann Kreyenborg (1889–1963), and ornithology Professor Johannes Thienemann (1863–1938), who were interested in the relationship between humans and animals, nature, ornithology, and art of falconry.[37] Following the German example, falconry associations were created in multiple European countries including Austria, Belgium, Bulgaria, Czech Republic, Denmark, Estonia, France, Georgia, Greece, Hungary, Ireland, Italy, Lithuania, North Macedonia, Malta, Norway, Poland, Portugal, Romania, Russia, Serbia, Slovakia, Slovenia, Spain, Sweden, Switzerland, the Netherlands, Turkey, Ukraine, and the UK. Currently most of these national falconry associations are connected under the umbrella of the IAF and Conservation of Birds of Prey, which now consists of 110 associations from 87 countries totaling 75,000 members.[6]

Besides practicing falconry, the main goals of the associations in the 20th century consisted in the protection of birds of prey. This latter has been promoted by the dramatic decline of raptors due to environmental pollutants (especially the organochlorine pesticide dichlorodiphenyltrichloroethane [DDT]) in large parts of the world during the 1960s and 1970s.[37,38] This led to attempts at captive breeding of birds of prey, which were successfully achieved in peregrine falcons in 1942/1943 by Renz Waller (Germany) for the first time. As a result of international veterinary and biological research and collaboration between scientists and falconers, large steps in captive propagation were taken in the 1970s by development and improvement of assisted breeding using artificial incubators, optimized aviary design, and the implementation of semen collection and AI. At that time, in Germany systematic breeding programs were initiated for the dramatically endangered peregrine falcon and the white-tailed eagle *(Haliaeetus albicilla)*. As a remarkable achievement, in the following four decades DFO members bred more than 2,500 peregrine falcons, of which more than 1,100 have been released into the wild via reintroduction programs to reestablish the almost extinct wild population.[37]

FALCONRY IN EUROPE—THE PRESENT

In continental Europe, various ways and fashions of falconry are practiced, defined as hunting of wild quarry in its natural habitat and state with a trained raptor. A valid falconry license after passing hunting and falconry examinations is required by law to practice falconry and to keep raptors in several European countries. Most falconers keep and train one or two raptors for hunting. The birds of prey species used for falconry include falcons for so-called "high flights" and buzzards, hawks, and eagles for so-called "low flights."

The most common and traditionally trained falcon species in several European countries is the peregrine falcon, followed by the gyrfalcon and the saker falcon. Less common is the use of lugger or lanner falcons for falconry. Hybrids obtained from cross breeding of falcon species were popular in the last decades, bred in large numbers because of the high international demand, mainly from the Middle East, but are decreasing due to prohibition of keeping and breeding most hybrid birds of prey in several European countries such as Germany. Merlins, prairie falcons *(Falco mexicanus)*, and aplomado falcons *(Falco femoralis)* are also rarely kept as hunting birds, most likely because of their limited availability due to a low number of breeders within Europe and limited import numbers. Moreover, most songbird species (e.g., different passerines such as thrush [*Turdus* spp.], starling *[Sturnus vulgaris]*, or lark [Alaudidae]), which are the usual prey of merlins and aplomado falcons, are not legalized for hunting and are protected by nature conservation law in many European countries. The previously mentioned larger falcon species are appointed to hunt upland game such as pheasants, quails, partridge, grouse, and waterfowl such as ducks. Facing a steady decline of these traditional game species in many European countries, there has been an increase in numbers of carrion crows, rooks *(Corvus frugilegus)*, Eurasian magpies *(Pica pica)*, gulls (*Larus* spp. and *Chroicocephalus ridibundus*), and smaller geese (e.g., *Alopochen aegyptiaca* and *Anser anser*) as preferred quarry for European falconers. Releasing falcons from the falconer's glove to catch prey during walking or riding is not very common anymore except in a few regions of the continent. Especially for the hunting of carrion crows, releasing the falcon from the window or roof of a moving car is more established. In contrast to gun shooting, hunting with birds of prey out of a vehicle is allowed in several European countries as long as the falconer adheres to driving laws. The falcon should follow the crow, propelling itself forward fast and catch it in pursuit flight. Alternatively, the falcon may drive the crows into a tree and hem them there. The falconer's duty is to assist his falcon by frightening the crows through shouting and making noise using rattles/flappers and thus to make them flee away from the tree. The experienced falcon will wait-on in favorable altitude ready to stoop down to the fleeing crows and catch them during nosedive or pursuit flight. This more modern way of hunting with falcons needs to be different from the traditional waiting-on techniques to hunt game such as pheasant, quail, or grouse. For this purpose, a well-trained hunting dog is crucial. Pointing dogs such as setter and pointer breeds from Germany (e.g., Munsterlander, Pudelpointer, German Shorthaired Pointer, German Longhaired Pointer, or Weimaraner), France (e.g., Epagneul Breton/French Brittany), Great Britain (e.g., English Pointer, Gordon Setter, English Setter, or Irish Setter), or Hungary (e.g., Vizsla) are widely distributed among falconers in Europe. The dogs need to be trained to freeze on point as soon as they scent the game and only to flush it out upon the falconer's signal. The signal is given when the waiting-on falcon manages to reach a suitable altitude and a promising hunting position. The falcon performs a stunning downward stoop with the wings folded tight to its body in teardrop-like form, reaching a high velocity when the game takes flight and finally catching it in a cloud of feathers—a moment which is fascinating for everyone witnessing. As this way of hunting requires perfect training of the hunting dog, perfect training of the falcon, and cautious familiarization of both animals to form a winning team with the falconer, bird of prey, and

dog, this is legitimately regarded as the supreme discipline of falconry.

With hawks and buzzards, smaller-sized mammals (e.g., rabbits, hares, and in some countries, squirrels [*Sciurus* spp.]) and birds (e.g., carrion crows, pheasants, ducks, moorhens, and small geese) are caught. An exception because of its small size and its prey (only small birds to the size of magpies, doves, or pigeons) is the sparrowhawk. The so-called "spar" has always been a popular and fascinating hunting bird in Europe. Training and keeping of the tiny, but brave and acrobatic spars require much experience because weight management is particularly difficult in this small-sized raptor. Due to nature protection laws in many European countries, the hunting quarry of sparrowhawks is strictly limited to a few common bird species such as magpies and wood pigeons *(Columba palumbus)*. Because of this, in some countries, the keeping of a sparrowhawk is currently not permitted; however, in Germany its use for falconry has been legalized since June 2018.

The most common hunting bird in Europe for centuries is the Eurasian goshawk, even though North American hawk species, especially the Harris's hawk, but also the red-tailed hawk *(Buteo jamaicensis)*, are flown in increasing numbers by European falconers. Emperor Frederick II called the goshawk a perfect bird for the kitchen, able to hunt everything that is needed for a delicious meal. With its dark red eyes, the goshawk is a formidable creature, fast and skilled to kill all prey of appropriate size. Other medium-sized species seen occasionally as hunting birds include ferruginous hawks *(Buteo regalis)* and long-legged buzzards *(Buteo rufinus)*. Hunting carrion crows with the broad-winged birds out of vehicles is usually much shorter in distance compared to the hunt with falcons. In contrast to falcons, the quarry is more diverse, including medium-sized birds and mammals. Hunting usually is performed directly off the falconer's glove while walking or from a tree or an elevated perch while having the birds follow-on and lead. The prey is scared up by the falconer or assisting persons out of bushes, grasses, or reeds, but preferably by flushing dogs (Figure 55.12). The attentive hawks are swift to react and may reach incredible acceleration to catch up rapidly to fleeing prey. In Europe the use of German (e.g., German Wirehaired Pointer, German Shorthair Pointer, German Longhaired Pointer, Pudelpointer, Weimaraner, and Munsterlander), French (e.g., Epagneul Breton/French Brittany), English (e.g., English Setter), Italian (e.g., Bracco Italiano), or Hungarian (e.g., Vizsla) flushing dog breeds is popular. If hawks and dogs are familiarized, they may form an unbeatable team (Figure 55.13). For hunting rabbits *(Oryctolagus cuniculus)* ferreting is also an established technique in Europe. Tamed ferrets *(Mustela putorius furo)* are inserted into the burrows to scare up the rabbits and make them escape to the surface, where the hawks are able to catch them. Small bells are attached to the ferret using collars to increase the rousing efficacy and to prevent the ferret from catching the rabbits by itself. Efficacy may be increased by using a dog to indicate which burrows are containing rabbits and offering more promising hunting chances.

Eagles are also commonly used in European falconry; however, their number is low compared to hawks and falcons. By far the most popular eagle species is the golden eagle, as it inhabits several mountain regions within Europe and has been used as a heraldic symbol of strength and power. Thus the golden eagle is the national symbol of several states such as Austria, Poland, Czech Republic, Russia, and Germany (even though the white-tailed eagle is most likely the real model for the heraldic symbol of Germany). In these countries, hunting with golden eagles is regularly practiced to hunt for hare (Figure 55.14), red fox, and roe deer *(Capreolus capreolus)*. Besides the golden eagle, African hawk eagles *(Aquila spilogaster)*, Bonelli's eagle *(Aquila fasciata)*, and Chilean blue eagles *(Geranoaetus melanoleucus)* are less common. The ornate hawk-eagle *(Spizaetus ornatus)*, African crowned eagle *(Stephanoaetus coronatus)*, and martial eagle *(Polemaetus bellicosus)* are rarely seen as hunting birds in Europe. Eagles are usually started from the fist during walking or more seldom riding in open fields. Prey is flushed out by the falconer or assisting persons or by flushing dogs as mentioned previously. Hunting flights

FIGURE 55.12 Hunting with goshawks or broadwings is usually performed directly off the falconer's glove while walking. The prey is scared up by the falconer or by flushing dogs out of bushes, grasses, or reeds. Here a Harris's hawk *(Parabuteo unicinctus)* and a Hungarian Vizsla support the falconer. (Photo courtesy Claas Niehues.)

FIGURE 55.13 Hawk, flushing dog, and falconer form an unbeatable team during hawking. Here the Eurasian goshawk *(Accipiter gentilis)* is taken back to the falconer's fist and rewarded by offering a pigeon wing after successfully hunting a rabbit that has been flushed out by the Hungarian Vizsla. FIGURE 55.14 Golden eagles *(Aquila chrysaetos)* in Europe are trained to hunt for hare, red fox, and roe deer. Here, a golden eagle caught a European brown hare *(Lepus europaeus)* and is still full of adrenaline after the hunt. (Photo courtesy Gerhard Bühler.)

of the majestic eagles are sometimes long, but powerful and formidable.

The main hunting season in Europe is during autumn, winter, and spring (usually September–March). During this time falconers go for hunting, either alone with their animals or in small groups of a few falconers. These hunts are also an integral part of falconer meetings such as the annual meetings of the national falconer associations. Except for Harris's hawks, which may be used to fly and catch as a pack, in a hunting group a previously agreed order of flights and self-discipline of the participating falconers are very important to ensure that only one bird is flying toward the quarry at any one time.[39] Otherwise one bird may injure or kill the other bird, which must be prevented. It is an unwritten ethical rule that a falconer generally should not hunt more than three creatures per hunting day to not overwhelm the hunting bird and the capacity of the habitat. Traditionally, in some countries, especially in Germany, France, and Austria, hunting-horn music is played to greet falconers and their animals when they arrive at the meets, but also when they depart to the field to hunt, and to honor the prey as it is laid out by firelight or torch at the end of the hunting day (Figure 55.15). Usually, talks, workshops, and a celebratory feast are also included in these annual meetings.

Nowadays, falconry in Europe is mainly practiced as a hobby. Only a minority of falconers are employed as professional falconers. Pest control companies (e.g., for the food industry), urban parks, sport facilities, and cemeteries, for the protection of dykes, historic buildings, or agricultural crops are some of the working tasks for professional falconers. Moreover, falconers are often in charge of bird control at airports to reduce the risk of bird collisions with airplanes. Besides this, there are multiple areas where the use of guns is prohibited or inappropriate in most European countries. At these places, falconry offers an efficient, quiet, and well-accepted alternative for hunting. Professional falconers are also employed at places with falconry displays such as wildlife parks, zoological institutions, and falconry centers. Even though "real falconry" in the sense of hunting is not

FIGURE 55.15 To honor the prey, it is laid out by firelight or torch at the end of the hunting day. Traditionally, hunting-horn music is played during this celebration in Germany, France, and Austria. (Photo courtesy Dominik Fischer.)

performed and not demonstrated to the public, methods, techniques, and equipment are used according to falconry to train and keep raptors. In several European countries, mainly Austria, France, Spain, and Germany, falconry displays are established in historic castles addressing the history and the romantic connection of knights, kings, and falconers in medieval times.[36] The history of bird of prey centers in Europe dates back to 1939 when the "Adlerwarte Berlebeck" (German for "eagle center Berlebeck") was opened to the public in Germany. This was followed by wildlife parks such as the "Wildfreigehege Hellenthal" (German for "Wildlife Park Hellenthal"), where falconry displays were first established as an integral part of zoological institutions. Nowadays, these institutions still play an important role in environmental and biological education (Figure 55.16). They offer a unique

FIGURE 55.16 Falconry displays are established at historic castles or in zoological institutions. They still play an important role in environmental and biological education and offer a unique option to transmit information about falconry, birds of prey, their current situation and threats, as well as options to protect them as part of the environment. Here a black-chested buzzard-eagle (*Geranoaetus melanoleucus*) is landing on the falconer's fist at Bird of Prey Center in Hellenthal, Germany, in front of the public and a cinereous vulture *(Aegypius monachus)*. (Photo courtesy Hermann-Josef Baumgarten.)

option to convey information about falconry, birds of prey, their current situation, and threats, as well as options to protect them as part of the environment. Therefore these institutions play an important role for falconry and birds of prey and manage to increase public acceptance and fascination for these unique and extraordinary creatures.

Captive breeding of birds of prey is practiced by European falconers, as taking birds from nature is strictly limited or completely prohibited and CITES regulations have been implemented since the late 1970s in European countries. Most falconers breed small numbers, with the offspring being intended to be given to falconer colleagues. In addition, there are a few large commercial breeders, especially of large falcons and goshawks, who sell the offspring internationally to all parts of the world. Large breeding facilities exist, for example, in Germany, Austria, and Spain, regularly breeding falcons for the Middle East. However, some raptor species are bred not commercially and donated for reintroduction projects by falconers. After the successful reintroduction of peregrine falcons in Sweden and Germany, Polish falconers are now dedicated to the reintroduction of this species in Poland and to the restoration of a tree-nesting population. Other reintroduction programs in Europe include eagles (e.g., white-tailed eagles), vultures (e.g., bearded vultures *[Gypaetus barbatus]*), and owls (e.g., Ural owls *[Strix uralensis]*). In these projects, falconers cooperate with zoos, wildlife parks, and breeding centers. Moreover, European falconers from Germany, Belgium, Spain, Austria, and the UK cooperate in international species conservation projects such as the "Project Lugger," an IAF-supported initiative to save the Asian lugger falcon (http://projectlugger.com/).

As falconers are experienced in keeping, feeding, nursing, treating, and training birds of prey, they are regularly involved in veterinary-guided rehabilitation of sick or injured raptors. In some countries, the national falconer associations run their own rehabilitation centers for this purpose. After successful medical treatment of a bird of prey, falconers are in charge of subsequent individual physiotherapy and species-specific training using falconry methods as important preparation for releasing these birds to the wild.[40] Some European falconer associations support scientific studies to optimize falconry training methods and to evaluate the true benefits of these measures for the rehabilitation of birds of prey. Currently, the veterinary knowledge that falconer-veterinarians have accumulated and published provides the basis for treatment and rehabilitation of many injured wild raptors. Furthermore, falconers contribute widely to knowledge of wild raptor ecology and management in Europe.

National initiatives for rehabilitation, species conservation, or animal welfare are coordinated and supported within Europe by the European Foundation for Falconry and Conservation (EFFC) (https://www.ef-fc.org/) or internationally by the IAF. In recognition of the intensive commitment to nature conservation in general and to birds of prey in particular, some European falconer associations, such as the DFO, have been recognized as nature conservation associations by national governments. Moreover, following the inclusion in UNESCO's Representative List of the Intangible Cultural Heritage of Humanity, falconry has been included as a living human heritage in the nationwide directory of Intangible Cultural Heritage in several European countries (as mentioned earlier: Austria, Belgium, Czech Republic, France, Germany, Hungary, Italy, Portugal, and Spain).

FALCONRY IN EUROPE—THE FUTURE

Future falconry in Europe will need to keep on focusing on conservation, animal welfare, culture, and education to be preserved as a sustainable, sophisticated, silent, and most natural art of hunting and as an incomparable, respectful, and passionate relationship to magnificent and wild living creatures.

Falconers need to continue to develop knowledge about husbandry, training and nutrition, reproduction, health, and disease in raptors and animal welfare using a strong and international cooperation with veterinarians and scientists from different disciplines. Facing large declines in both raptor species and game species, conservation will need to focus on a holistic approach involving hunters, falconers, scientists, nature conservationists, farmers, foresters, politicians, and the public to collaborate toward the common goal of environmental protection and biodiversity. Initiatives such as the IAF-supported conservation of free-ranging partridge populations ("Perdix Project") are one bullet point on the to-do list. Improvement of habitat structure, increase of food availability, and reduction of disturbances and stressors are important steps to reach this goal. Besides these measures, efforts for the individual rehabilitation of injured or sick raptors will also be an important task of future falconers in Europe.

Existing conflicts with civilization and human development (e.g., through farming and forestry, construction, pollution, disturbance, and climate change) are difficult tasks to solve in Europe. Falconry offers a unique method for sustainable use of natural resources and an ethically acceptable means of meat production by using a natural method of predation with a negligible risk of prey escaping with deadly injuries (compared to shooting) and offering a faithful alternative to intensive livestock farming. Hopefully in the future, there will still be a demand for such sustainable and ecological use of wildlife as indicated by a promising tendency in European society during recent years.

After banning several pesticides with toxic potential in the past, a current and future task is the refinement and optimization of energy sources, such as electricity transmission lines (power lines) and power plants (wind turbines) in order to reduce mortality in bird of prey populations. In this regard, the discrepancy between environmental protection attempting to decelerate climate change and species conservation is problematic. Other conflicts addressing the economy, such as the reduction of pesticides in agriculture or the use of drugs in livestock (e.g., use and deposition of the cheap but dangerous diclofenac), will require continuing attention and constant lobbying. Lobbying, transparency, and public education will also be required to positively influence legislation. To achieve reasonable legislation and guidelines on all aspects of falconry, falconers will need to be confident, but self-critical in a continuous dialogue with different stakeholders. The permission of falconry in Scandinavia will be a stage finished in the short term in Europe; this was achieved in Denmark in 2019 and will hopefully be achieved in Finland and Norway soon. Most likely, in future, falconry will meet with resistance from animal rights initiatives, which aim to terminate keeping of animals, especially of exotic and "wild" animals and try to abolish hunting. To defend falconry from

these threats, public relations activities, publications, and environmental education are most important. In a society that has drifted away from nature and the environment, this is now already crucial. However, facing future generations that did not learn to live with animals and did not get used to food production in terms of agriculture and hunting, this will be even more important to be accepted by society. In this regard, it will be important that falconers are honest and transparent, keep on explaining falconry, and always endeavor to strike the right note. Falconry has been practiced in Europe for over a millennium, but it will be a tough task handing the art and tradition of falconry down to future generations.

FALCONRY IN THE UK—THE PAST

> *As the ox hath his bow, sir, the horse his curb, and the falcon her bells, so man hath his desires.*
>
> **Shakespeare,** *As You Like It*, **Act 3, Scene 3**

Falconry—defined as the art of hunting with a trained bird of prey—is very much now considered a sporting activity in the UK. Historically a hunter would train a bird as a way of obtaining food, and food acquisition was almost certainly the origins of falconry. Historic artifacts and archaeological evidence links falconry in the UK as far back as the late sixth and early seventh century.[41] While falconry was likely practiced among all classes of people living in the UK, it is the medieval kings and nobles whose falconry pursuits we have the greatest documentary evidence. In the eighth century extracts from Cook record Aethelbald, King of Mercia, being sent a hawk and two falcons by Boniface, Archbishop of Mayence. Harold, Earl of Wessex and later King of England, is depicted with hawks on the fist in the Bayeux Tapestry dating from the 11th century. It was common practice for armies to take hawk and hounds on campaigns so knights could relax between battles.[33] A famous and frequently reproduced list of birds that could be flown according to social standing is shown in Table 55.2. Despite this list being republished frequently, there is little evidence of it being strictly adhered to, although there is probably some accuracy in the fact the rarer and more exotic raptors were only available to those of sufficient social standing.

In more recent history, falconry has become increasingly accessible. Falconry clubs traditionally provided a route into the sport and the British Falconers' Club was founded in 1927, by the surviving members of the Old Hawking Club (itself founded in 1864). The Club is the oldest and largest falconry club in the UK. A large number of smaller regional hawking/falconry clubs exist across the UK.

Falconry centers have become common across the British Isles, with the first opening in Gloucestershire in 1967. Originally termed The Falconry Centre and now named the International Centre for Birds of Prey (ICBP), it was opened by Phillip Glazier, a preeminent falconer of the time. Over the last 50 years, these falconry centers have exposed great numbers of the public to birds of prey and have helped build the popularity of falconry among the general public. Centers such as ICBP have also contributed to raptor conservation worldwide and had some of the earliest success in captive breeding.

FALCONRY IN THE UK—THE PRESENT

Rough estimates put the number of bird of prey keepers in the UK at between 15,000 and 25,000. Unlike some countries such as the United States, no license system currently exists for falconry. Many of these owners will, however, not participate in falconry in its truest definition—hunting naturalized quarry with a trained bird of prey. A number of other falconry-related activities have developed—these include display falconry, lure flying, ro-falconry, and pest control.

The number of species used in falconry in the UK is incredibly varied. Until 2020, no licenses for the wild-take of birds had been granted for several decades, and UK falconers were entirely reliant on captive breeding to provide birds for use in falconry. The justification for recent licenses was to take wild birds to ensure a healthy gene pool of birds for use in falconry.

TABLE 55.2

A Famous and Frequently Reproduced List of Birds That Could Be Flown According to Social Standing

Social Status	Raptor Flown According to Social Standing
Emperor	The eagle, vulture, and merloun
King	The ger falcon and the tercel of the ger falcon
Prince	The falcon gentle and the tercel gentle (peregrine)
Duke	The falcon of the loch (peregrine)
Earl	The falcon peregrine
Baron	The bustard (harrier?)
Knight	The sacre and the sacret
Esquire	The lanere and the laneret
Lady	The marlyon (merlin)
Young man	The hobby
Yeoman	The goshawk
Poor man	The jercel (kestrel)
Priest	The sparrowhawk
Holy water clerk	The musket
Knave or servant	The kestrel

Primarily two rearing methods are used to raise young birds—imprinting (hand-rearing) or parent-rearing. There has certainly been an increase of imprint birds being flown in recent years in the UK. Falcons, accipiters (true hawks), broadwings, and eagles are all flown. For traditional falconry, the bird selected is typically matched to the surrounding land to which the falconer has access to hunt. The UK has varied landscapes—farmland, 56%, and natural landscapes (forestry, heather moorland, grassland), 34.5%. For example, flying majestic peregrine falcons in closed country just will not work effectively, with accipiters being far more suitable in these situations.

Broadwings

Harris's hawk

By far the most popular bird in UK falconry, the Harris's hawk was originally imported from its natural range of South and Central America and southern United States in the 20th century. Its biddable nature, relative ease of training compared to more highly strung birds such as accipiters, and social behavior have made them incredibly popular. They are versatile hawks and have quickly overtaken the common buzzard *(Buteo buteo)* as the broadwing bird most commonly used in UK falconry. Their nature has also made them excellent birds when used in pest control and display falconry.

Red-tailed hawk

Another North American species, the red-tailed hawk, is a larger and more powerful hunter than the common buzzard and has a modest popularity in UK falconry. Hybrid birds are fairly common, with ferruginous hawk × red-tail hybrids being particularly popular—with flight similar to a small eagle, they are versatile hunters.

Other broadwings commonly flown include the ferruginous hawk and common buzzard.

Falcons

See section on Falconry in the Middle East—The Present.

Accipiters—Shortwings

These are primarily woodland birds and incredibly agile. Traditionally considered highly strung, modern imprinting techniques and rearing methods have been very effective when training accipiters.

Goshawk

The goshawk is the most frequently flown shortwing in UK falconry and is the classic accipiter. These are great all-round hawks, traditionally named the "cook's bird" due to their versatile nature as a hunter and ability at catching game.

European sparrowhawk

One of the most exciting birds in falconry—they are fast and without fear—often taking game far larger than themselves. They prey on a wide range of small- or medium-sized birds. Their preferred quarry—the common blackbird *(Turdus merula)*—requires a license to hunt in the UK. Sparrowhawks have high metabolic rates and careful management from the falconer is required to keep them in ultimate condition. Imprinting has greatly improved the success when hawking sparrowhawks in the UK and almost all birds now flown are hand-reared.

Other accipiters occasionally used in UK falconry include the Cooper's hawk *(Accipiter cooperi)*, black sparrowhawk *(Accipiter melanoleucus)*, and African goshawk *(Accipiter tachiro)*.

Eagles

Eagle falconry is a very specialist subsection of UK falconry. The iconic golden eagle is the most prevalent eagle in UK falconry and being a native species is best adapted to the cold weather and frequent high winds during the traditional falconry season. Typically hunting small- to medium-sized mammals, eagles can fly in both a pursuit and waiting-on style, offering contrasting but equally spectacular flying.

Training Methods

Lure flying

In the UK, the traditional method of training a falcon was to the lure. The lure—typically constructed of a leather pad—sometimes with the addition of wings, simulates prey, which the falcon must hunt. The falconer swings the lure to simulate an "evade and capture" scenario. Training in this method has the potential to become somewhat one-dimensional. As well as being used as part of fitness training, a lure can also be used to attract a falcon or hawk to be reclaimed onto the fist.

Robotic prey

In the last 5 years, simulated hunting scenarios with robotic prey have become increasingly used to train birds. Planes designed to replicate commonly flown species constructed of polystyrene are flown. The planes have internal propellers to prevent injury and allow the falcon or hawk to strike the model in the air—as opposed to planes pulling a lure, which were traditionally used. These models are increasingly used in raptor rehabilitation and have shown promise with building fitness and hunting ability for injured raptors—particularly eyass birds with limited or no hunting experience (Figure 55.17).

For the imitation of terrestrial prey species, rabbit, fox, and hare lures dragged on a pulley system are used mainly by hawk and eagle falconers. Multiple flights in a short space of time build fitness and teach birds to be observant and reactive. Flights including uphill gradients are particularly beneficial at building strength and stamina.

FIGURE 55.17 Hybrid falcon binding to a robotic houbara model during training.

FIGURE 55.18 Gyr saker falcon pursuing a robotic crow model during a race competition.

Modern machines are remote-controlled and can be very portable to allow the replication of various different hunting simulations. In comparison to traditional training this is far more mentally stimulating—particularly for accipiters and can lead to improved temperament (Figure 55.18).

Drones

To help encourage inexperienced falcons to obtain a suitable pitch (height held above the falconer before the stoop), drones are now being frequently employed. The benefit of a drone compared to a plane is it is far easier to maneuver and fly. A lure can be suspended a safe distance below the drone to attract the falcon upward. As training progresses, the drone is flown at increasing heights to encourage the bird to quickly ascend to a pitch, which provides a spectacular stoop. The best drones have covered blades.

Pest Control

Falconry birds are now routinely used for bird abatement as part of pest control activities in the UK. While traditionalists would certainly not call this falconry—with that term being saved for when a bird is used in hunting activities, pest control work has allowed people to turn flying birds from a hobby into a job. Airports, sporting stadiums, rubbish dumps, food stores, warehouses, and shopping centers, all routinely employ falconers. Harris's hawks and large falcons, particularly gyr × saker hybrids, are the most commonly used species.

The use of Harris's hawks to scare pigeons from the famous grass tennis courts at Wimbledon makes the press year on year—it has been an opportunity to promote the other positives of falconry, other than sporting activities.

Falconry Displays

For many of the UK public, the first experience they ever have of falconry birds is the displays provided at centers and game fairs throughout the UK. Although the Falconry Centre in Gloucestershire was the first, a large number of other centers have been established since. The opportunity to see birds fly close-up aims to give the public an appreciation of raptors and sympathize with their wild conservation efforts. Some of the larger falconry centers also participate in conservation breeding of critically endangered species.

FALCONRY IN THE UK—THE FUTURE

Falconry is still very popular in the UK—with most estimates suggesting a growing number of participants over the last 10 years. Current estimates are of around 25,000 UK falconers. Despite a growing popularity, it is still very much a niche sport and does not carry the same support as other field sports such as shooting and angling. The greatest threat to UK falconry comes from animal rights activists and the risk of legislation banning or severely restricting falconry activities. In 2016, falconry was inscribed by UNESCO as an Intangible Cultural Heritage of Mankind. Unfortunately, at the time of print the UK does not recognize this, and as such, the UNESCO status of falconry provides little protection to UK falconry.

Tethering of birds of prey frequently attracts criticism—and while most falconers would consider a period of tethering necessary for many species of raptor (and essential when flying large eagles or accipiters), the excessive or unnecessary tethering of birds, particularly when not regularly flown, is difficult to defend. It must be remembered that birds flown in falconry experience a freedom to perform natural behavior that can be matched by very few other captive birds.

Many falconers and falconry centers already contribute heavily to conservation. In the future, techniques developed for falconry purposes should and likely will be increasingly used in the rehabilitation and release of wild injured raptors (Figure 55.19). Captive reproduction may become an important part of conservation efforts for critically endangered species, particularly African and Asian vultures.

FALCONRY IN NORTH AMERICA—THE PAST

> *We are all entangled in this web of life. It is inescapable. Falconry is a link to our past and a guide to our future, and for some, it helps illuminate the mystery of purpose on earth.*
>
> **Ed Pitcher, 1991**

Falconry in the United States of America

Falconry is a challenging and unique sport, but it did not gain significant popularity in the United States until the early to

FIGURE 55.19 A robotic crow model converted for use as a hack station during the soft release of a rehabilitated peregrine falcon *(Falco peregrinus)*.

mid-1900s. While it began as a utilitarian activity in other regions of the world, it developed into an art form in North America. From the 18th century and to this day, success and achievement are measured more by the quality of the flight than the taking of game.[42–44] Given its effectiveness in providing table fare in many cultures worldwide, it is surprising that there is very little evidence that Native Americans practiced falconry in any form. However, there are reports that Native Americans used similar methods to those used by falconers to capture eagles for ceremonial use.[45,46] Benedict-Henry Revoil described hunting herons with Black-Foot Indians in 1844,[47] and British literature suggests that Native Americans understood the practice of taming birds and demonstrated interest in the sport.[48]

In Colonial America, there appeared to be interest in falconry, although much of the interest seemed to concentrate on exportation of raptors from the "New World" to Europe (England) in the early to mid-1600s.[45] Settlers in the Virginias (Jamestown) and Carolinas, as well as Dutch settlers in what is now New York, also expressed interest in falconry in the 1600s.[44,49] Even "thirty-five years before the Mayflower brought the Pilgrim Fathers to New England, the colonists of Sir Richard Grenville on Roanoke Island were training hawks."[50] Descriptions of falconry and its activities were scant in the 1700s and 1800s, although the second volume of the *American Turf Register and Sporting Magazine* in 1830 gave reference to the sport.[51]

The 1900s marked a significant increase in the interest of falconry in America, with several individuals supporting the increase. Benjamin Rose Hoffman of Philadelphia was interested in falconry and the British hawking method[44] and made several trips to England to participate in the events of Britain's Old Hawking Club. Paul J. Rainey, a very wealthy hunter and plantation owner in Mississippi, hired Englishman R. Bowring as a professional falconer.[44] Hoffman and Bowring communicated with each other on two occasions, in 1910 and 1911, and Bowring suggested that a falconry club was needed in the United States.[44] Born in Seattle, WA, and raised in Washington DC, a 16-year-old falconer by the name of Russell Luff Meredith wrote of his experience hunting with a sharp-shinned hawk *(Accipiter striatus)* pursuing English or house sparrows *(Passer domesticus)*.[52] Meredith, who would later graduate from the US Military Academy at West Point (Class of 1917) and retire as a US Army Air Forces Colonel (1927), is considered by many to be the "Father of American Falconry."[44] Others also wrote of their falconry experiences including Dan R. Gray of Rockdale, TN, who enjoyed hunting with a Cooper's hawk, then later a European goshawk, and sharp-shinned hawk.[53] Edward Breck in Nova Scotia was convinced that he was the first to train an American hawk and introduce falconry to the New World. Unfortunately, he would be disappointed to learn that he was not the first; Gray had written of his experiences training a Cooper's hawk prior to Beck's.[54] North American falconry experienced another surge of interest in the 1920s and 1930s, likely the result of exposure of Americans to falconry while abroad during World War I or improved economic conditions that allowed for more leisure activity.[44] One of the more important contributions to North American falconry literature was written by a non-falconer, Louis Agassiz Fuertes.[55] Fuertes' article, *Falconry: the Sport of Kings*, published in the December 1920 issue of *The National Geographic Magazine*, introduced the sport to a large audience, creating even greater interest by falconers and would-be falconers of all age groups.[44,55] In the late 1920s Captain Charles W.R. Knight, a charismatic English falconer, would travel and lecture about falconry and would fly Mr. Ramshaw, his golden eagle, during demonstrations.[44]

Even with increased interest in falconry, birds of prey were considered vermin in North America, and mass shootings of raptors occurred during the late 1920s and early 1930s, especially along their migratory routes, often occurring at Hawk Mountain, PA, and Cape May, NJ.[56] Autumn hawk shoots became tradition in North America and were the subject of *Hawks Aloft*, written by Maurice Broun,[57] who became the first keeper in what is now Hawk Mountain Sanctuary.[56] In 1934, the killing of raptors would stop at Hawk Mountain, and Hawk Mountain Sanctuary would become the nation's first refuge for birds of prey.

The 1920s and 1930s were marked by a surge in the number of falconry clubs in the United States. One of the most notable, the American Hawking Club was located in Brewster, NY. The American Hawking Club hired a falconer, Frank Levy, who was a recent graduate of Cornell University and associate of Fuertes.[44] During the early 1900s, fascination with the sport in the United States seemed to grow more from a naturalist perspective, rather than concerns about the traditionalist views of falconry noted in other parts of the world.[44] Alva G. Nye, Jr., and twin brothers Frank C. Craighead, Jr., and John J. Craighead became acquainted with Frank Levy and soon became falconers.[44] The Craigheads' father was an environmentalist, and their sister, Jean Craighead George, became a very well-known author of children's books. Her novel *My Side of the Mountain* introduces Frightful, a peregrine falcon taken by Sam, the main character, and trained to catch frogs, pheasants, rabbits, and sparrows. Frank and John Craighead would gain further prominence through their articles published in *National Geographic Magazine* and their book *Hawks in the Hand* (1939, 1997).[44]

The Peregrine Club, founded by James N. Rice II in 1936, would replace the short-lived American Hawking Club. The Peregrine Club was also short-lived but provided its members the opportunity to share ideas and information and became a blueprint for future falconry clubs in North America.[44] In 1938, Colonel Meredith proposed the formation of a national falconry club at North America's first falconry meet in Media, PA, and the Falconers Association of America was formed. Difference of opinion regarding logistics with this club led to the formation of the "Falconers Association of North America," which published the *American Falconer Journal*.[44] Unfortunately, World War II Pearl Harbor put an end to the club's activities.[44] After World War II, the Falconry Club of America was formed and grew quickly. Similar to the Falconer's Association of America, differing opinions within the Falconry Club of America lead to the formation of the North American Falconer's Association (NAFA) formed in 1961.[44] NAFA's first president was Hal Webster, a young falconer who became interested in the sport in the 1930s. Hal and his good friend Frank L. Beebe, a Canadian falconer, would be forever linked together as cofounders of NAFA as well as authors of one of the seminal texts on the natural history, capture, training techniques, and breeding of raptors

used in falconry. This text, *North American Falconry and Hunting Hawks*, was first printed in 1964 and would become required reading for anyone interested in or already practicing falconry in North America. Since its early beginnings, NAFA has represented falconry in North America on both the state and federal levels. The effectiveness of NAFA in garnering membership for North American falconers stems from the opportunities it provided its members. NAFA publishes articles written by falconers as well as provides members access to numerous articles about falconry in the *Hawk Chalk* and the annual *Journal of the North American Falconer's Association*. Social events such as regional and national field meet regularly provide falconers with the opportunity to get together.

While falconry was seemingly predominant along the eastern United States, young men and women around the country began to show interest in the sport. Of note, Bill Russell, a medical student, became interested in falconry and would later author one of America's first falconry books, *Falconry: A Handbook for Hunters*.[58] Another noteworthy individual was Fran Flint, a graduate student of Aldo Leopold, who many consider the father of wildlife management and the American conservation movement.[44] Fran would later marry Frederick Hamerstrom, and together they would provide the foundation for many of the laws and regulations protecting raptors and the recognition of falconry.[44] In 1948, Harry McElroy, a young falconer living in Houston, TX, would begin his falconry journey flying Cooper's hawks. McElroy and many others that began practicing falconry at this time would gain prominence in American falconry and become innovators of falconry training, weight management, and imprinting techniques still used to this day. In 1989, McElroy would establish a home in Mexico for nearly 3 years, hunting aplomado falcons in Querétaro, Mexico.[59] McElroy would host Mexican falconers at his home and would contribute significantly to the knowledge of falconry in Mexico.[59]

Falconry in Canada

Falconry in Canada and its territories, as in the United States, is diverse, with many of its pioneers emigrating from other countries, some specifically for falconry (Mark Williams, personal communication, 2020). Definitive accounts of falconry being practiced in the New World, what is presently Newfoundland and Labrador, are difficult to find. Falconers could have been present during early explorations of these regions. Records exits of falcons being sent back to England as early as the 1500s. British Parliament enacted a reward system in 1503, resulting in the mass transplantation of falcons, likely highly prized gyrfalcons and peregrine falcons, from the New World back to England during the 16th and 17th centuries. One of the earliest accounts of the actual practice of falconry in Canada was published in the *British Sporting Magazine* and recounts the shooting of a banded raptor in Yorkshire, England. According to the band, the owner of the hawk was the Governor of New Halifax, America, in 1762.[60] In 1850, A.E. Knox described a British Colonel Johnson known to have taken two peregrines falcons that he allowed to fly from ship to ship during the Atlantic crossing.[61] Further, in 1871 Captain F. Sandys Dugmore describes having taken a team of hawks, to include seven merlins, two goshawks, and two peregrines, from Britain to Canada aboard the HMS Serapis in 1867.[44,62] In 1935, a young 18-year-old Ben Oswald Goodman Dixon emigrated from Scotland to Canada to attend McGill University. Ben was the nephew of famed British falconer William Herbert St. Quintin.[44] John Campbell also immigrated to Canada in 1954 after serving in World War II.[44] A falconer prior to World War II, Campbell did not practice falconry again until 1954 (Mark Williams, personal communication, 2020). John Campbell, American falconer Dr. Mike Person, and other Alberta falconers pushed for legalized falconry in the Province (Mark Williams, personal communication, 2020). Importantly, Campbell was one of the first falconers to breed peregrines and merlins in the 1972/1973 season (Mark Williams, personal communication, 2020). In the early 1950s, Frank L. Beebe began to actively participate in falconry and trained his first falcon.[44] Frank Beebe gained prominence as a falconer, writer, wildlife illustrator, conservationist, and an outspoken advocate for falconry. Frank viewed raptors as a renewable resource and was critical of regulations governing falconry in North America.[44,56] He was instrumental in cofounding NAFA and coauthoring *North American Falconry and Hunting Hawks* with his good friend Hal Webster. Beebe would also author several other important contributions to North American falconry, among them are *A Falconry Manual* and the *Compleat Falconer*, and contributed significantly to our knowledge of *F. p. pealei* and gyrfalcons.

Falconry in Mexico

Prior to the arrival of the Spaniards, more specifically Hernado (or Hernán) Cortés in 1519 to "New Spain," what is now Mexico, and his subjugation of the indigenous peoples, there was no evidence that falconry was practiced in Mexico.[44] There are reports that ninth Aztec Emperor Montezuma (1466–1520), imprisoned by Cortés, may have practiced falconry; however, those accounts were misinterpreted.[44] Reportedly, Montezuma was knowledgeable about wildlife management and had a zoo with a large collection of species at Tenochtitlan.[59] Within this zoo, Montezuma was reported to favor a section containing a large assortment of raptors possibly used for falconry; however, the full veracity of this has been debated.[34,59] Historian Jose Manuel Fradejas Rueda claims that a linguistic shift led to misinterpretation of the words originally written by Cortes by later writers and historians.[63] An account from Diaz del Castillo, one of Cortes' captains and author of *The True History of the Conquest of New Spain*, in 1575 describes a firsthand encounter in which it is clear that Montezuma did not know anything about training hawks.[64] Diaz del Castillo describes Montezuma's surprise that Cortes, Diaz del Castillo, Francisco de Acevdo, and other of Cortes' captains, upon seeing a small hawk pursue prey through the garden, discussed training and hunting with the hawk.[64] Montezuma subsequently ordered the hawk captured, and another captain, Francisco de Acevedo, subsequently trained it.[44] His training of this hawk likely represents the first hawk trained in the Americas.

A sentinel moment in Mexican falconry occurred on December 9, 1531, when the peasant Juan Diego had a vision in which the Virgin Mary appeared before him.[44] The description of his vision has become a major element in Mexico's religious beliefs and the Basilica of Our Lady of Guadalupe, which was built on the site of Juan Diego's vision.

In *The Mexican Hunter or Art of Hunting Mexico*, published by Pedro Blazquez in 1868, there is mention of the sport of falconry; however, it failed to mention if falconry was actually

practiced in Mexico. Similar to other regions of the Americas, there is little evidence to suggest that falconry was practiced in New Spain until the latter half of the 20th century.[44]

As in other areas of the Americas, there is little history of falconry in Mexico after the 16th century until the mid-20th century. In 1950, the Mexican Association of Falconry emerged in Mexico City.[59] However, similar to early attempts to create formal falconry organization in North America, the Mexican Falconry Association was short lived.[59] Letters and diplomas written by its president, and likely the only member of the Association, Guillermo José Tapia, provide evidence of existence (Raul Ducoing, personal communication, 2020). One such diploma was presented to Dr. Robert M. Stabler, who was only active for approximately 2 years then disappeared with no further records of him practicing falconry in Mexico (Raul Ducoing, personal communication, 2020). While one report suggests that the Mexican Falconry Association's membership included distinguished foreign falconers,[59] one falconry historian suggests that no records exist that others knew of the Association, and its founder also disappeared in 1951 (Raul Ducoing, personal communication, 2020).

The mid to late 20th century marked a surge in the interest of falconry in Mexico. In 1960, an 18-year-old falconer by the name of Roberto Béhar Calderó began practicing falconry in Coyoacán, Mexico City, by starting with a Harris hawk, and later a golden eagle.[59] Roberto was considered the initiator of falconry in Mexico and the first to import goshawks from Europe into the country.[59] Four years later, Rafael Del Valle Reyna started practicing falconry with a roadside hawk *(Rupornis magnirostris)*, a small *Buteo* that he used with a Vizsla to hunt quail.[59] Rafael is credited as being the first Mexican falconer to train the aplomado falcon and the bat falcon *(Falco rufigularis)*, as well as contributing to the Peregrine Fund's study and conservation project of the aplomado falcon.[59] In 1967, Ing. Federico Medrano Crespo, who would later become the president of the Asociación Mexicana de Cetrería in 1985, began his falconry experience by hunting rabbits with Harris's hawks and red-tailed hawks.[59] Eduardo Bessouda, Héctor and Eduardo Appellániz, Roberto Béhar, and Enrique Guerrero began hunting rabbits with Harris's hawks and red-tailed hawks and were documented as the first written accounts of hunting with hawks in Mexico.[59] Juan Carlos Rojo G., author of the *Falconry Heritage of Mexico*, learned about falconry in 1970 and started training an American kestrel *(Falco sparverius)*.[59] Most Mexican falconers hunted with Harris's hawks and red-tailed hawks; however, the flying of longwings did not occur until 1972 when Enrique Guerroro and Eduardo Appellániz trapped the first passage peregrine falcons in Mexico.[59]

The second Mexican falconry association, the Conservation and Investigation Center for Birds of Prey, was founded by Roberto Béhar in 1973 and located in Ajusco, a half hour from Mexico City.[59] This organization had approximately 10 members, which later grew to around 20 members in 1975.[59] During the same year, an article about falconry, written by Nicolas Trillo, was published in the *Shooting Hunting and Fishing* magazine and included a photograph of a hooded peregrine falcon. This article was the first to describe modern falconry in Mexico.[59]

What is described as the second generation of Mexican falconers came along in the late 1970s. In 1977, Raul Ducoing (Figure 55.20), considered one of the pioneers of falconry in Mexico and a historian of the sport, started by flying an eyass female kestrel and a tiercel passage American kestrel.[59] In 1978, the Investigation and Conservation Association for Birds of Prey (Asociación para la Investigación y Conservación de las Aves de Presa, AIPAP) was founded by its president, Luis Carino. Luis organized the first national conference for birds of prey at the National Autonomous University of Mexico, Mexico City, Mexico, which involved more than 40 falconers.[59] A second conference was held a year later at the same location, and by the end of the decade there were approximately 50 falconers in Mexico.[59]

FIGURE 55.20 Falconer and falconry historian Raul Ducoing is considered one of the pioneers of falconry in Mexico, and he, along with others, is leading the charge for falconry standards in Mexico. (Photo courtesy Raul Ducoing, used with permission.)

During the mid to late 1980s, several falconry associations would be formed in Mexico. In 1984, Juan Carlos Rojo G., Héctor Verdejo, Jorge Carbajal, and Franciso Vázquez started a new falconry association, the Asociación Mexicana de Cetrería (AMC).[59] The year 1986 would mark the occurrence of the first captive-bred peregrine falcon in Mexico. The AMC would change its name in 1989 to the Circulo Mexicano de Cetrería (CMC) and published an international bulletin, *El Halconero*.[59] The Asociación Cetrería de Toluca, another association, was founded in 1987 by Isaías de la Rosa, José Salazar, and Mauricio González.[59] Shortly afterward, the Association of Falconers and Protectors of Birds of Prey (ACPAP) was established in 1988. An attempt was made by the CMC to encourage Mexican falconers to unite in one national falconry group; however, that did not happen. Later, the CMC would become divided, and former members of the CMC would create the Federación Mexicana de Halconeria (FEMEHA) in 1990.[59] FEMEHA, along with falconry clubs, such as the Grupo Cetreros del Valle de Mexico, would host a number of meetings for Mexican falconers.[59] During this time the number of falconers in Mexico grew dramatically, and by the end of the 1990s, there would be 300 falconers in the country.[59] Unfortunately, FEMEHA was inactivated around 1996.

The 20th century would see a surge in the number of falconry clubs in Mexico, but it would also bring some challenges to falconry in Mexico. An initiative in the Mexican

Congress sought to change legislation (Article 85) and deny the registration and possession of birds of prey in captivity and prohibit falconry.[59] Mexican falconers, with support from NAFA and the IAF, united to defend their right to own and register raptors by sending numerous letters to the Mexican legislature.[59] Deputy Guillermo Tamborrel represented Mexican falconers in Congress, discouraged changes to Article 85, and halted the initiative. The benefit of Mexican falconers uniting for a common cause was the resurgence of FEMEHA in 2010.[59] FEMEHA would produce one Mexican falconry journal, *Volatería*, in 2017 that included a history of falconry in Mexico.[59]

The Peregrine Falcon in North America

As interest in falconry seemed to grow from a naturalist perspective, the voice of falconers became even more prominent in environmental issues and the plight of the peregrine falcon, bald eagle *(Haliaeetus leucocephalus)*, and other raptors in the mid-1900s. It was falconers who first noticed the dramatic decline and near extirpation of nesting populations of peregrine falcons, especially North American migratory species including the *anatum* peregrine falcon *(F. peregrinus anatum)*, sometimes referred to as the American peregrine falcon, and the Arctic or tundra peregrine falcon *(F. p. tundrius)*. Only the third species, the Peale's peregrine *(F. p. pealei)*, appeared to have stable populations but only those nesting along the north Pacific coast in Alaska and British Columbia.[65] The United States Fish and Wildlife Service (USFWS) did not consider peregrine falcons abundant, with studies in the 1930s and 1940s estimating 500 breeding pairs in the east and 1000 breeding pairs in the west and Mexico.[65] Canadian populations of peregrine falcons are difficult to document given the remoteness and difficulty of assessing populations in some areas. By the mid-1960s, populations of breeding peregrine falcons had been nearly exterminated from their eastern range. Western peregrine falcon populations did not fare much better, with populations declining by 80% to 90% in the mid-1970s.[65] In 1965, at the University of Wisconsin, Madison, WI, Professor J. J. Hickey convened an international conference intently focused on the rapid decline of peregrine falcons. The majority of attendees were falconers. It was determined that the unregulated use of organic pesticides, in particular DDT and its metabolites and breakdown products, dichlorodiphenyldichloroethylene (DDE) and dichlorodiphenyldichloroethane (DDD), caused eggshell thinning, resulting in dramatic population declines in peregrine falcons, bald eagles, and other avian fauna.[66–70] Sadly, a similar situation was experienced in Europe. These findings, and the indiscriminate killing of birds of prey, only exacerbated the decline of the peregrine falcon in the mid-1900s. Following Hickey's conference, falconers, biologists, academicians, educators, rehabilitators, and government biologists, all concerned about the welfare of peregrine falcons, officially incorporated the nonprofit Raptor Research Foundation (RRF) on February 11, 1966.[43,44] RRF's intention was to "to stimulate the dissemination of information concerning raptorial birds among interested persons worldwide and to promote a better public understanding and appreciation of the value of birds of prey."[71] More specifically, its members wanted to assess the status of the peregrine falcon and to discuss, promote, and exchange ideas on how to breed them in captivity.[71] NAFA established an affiliate North American Peregrine Foundation for raising money to fund work on the peregrine falcons,[43] and the RRF was influential in establishing several breeding and reintroduction centers. In 1970, Tom Cade, then a falconer and professor of Ornithology at Cornell University, enlisted the help of fellow falconers Jim Weaver, Bob Berry, and Frank Bond to create The Peregrine Fund.[43,44] The Peregrine Fund developed two programs, one in the east at Cornell University, and a second under the direction of falconer Bill Burnham, in Fort Collins, CO, and in cooperation with the Colorado Division of Wildlife.[43,44] The latter would be consolidated into a single location at Boise, ID.[43] *Falcon Propagation: A Manual of Captive Breeding* describes the methods, procedures, and equipment necessary for falcon propagation.[72] Additional locations were the Raptor Center at the University of Minnesota, where Dr. Patrick Redig and Bud Turdoff coordinated reintroduction of peregrines provided by falcon breeders, mostly falconers, into the Midwest.[43] The Santa Cruz Predatory Bird Research Group, founded in 1975 by veterinarian and falconer, Jim Roush, and marine biologist Ken Norris, bred and obtained falcons for reintroduction along the Pacific coast.[44] Meanwhile, in Alberta, Richard Fyfe, while working for the Canadian Wildlife Service, supervised Camp Wainwright, a captive breeding and research station, utilizing some of the last remaining wild peregrines in the area (Mark Williams, personal communication, 2020). The latter program was disbanded in the late 1990s when government funding was discontinued. Other smaller operations in Canada included one program coordinated by John Campbell and Wayne Nelson, a program at the University of Saskatchewan at Saskatoon coordinated two falconers Lynn Oliphant and Patrick Thomson, and lastly, one at the MacDonald campus of McGill University coordinated by Dr. David Bird who was not a falconer. In total, these successful operations accounted for the release of more than 6000 peregrine falcons back into the wild since 1974.[44]

The banning of DDT was central to the recovery of peregrine falcons in North America. Most notably, captive breeding and release of peregrine falcons by falconers preceded the ban of DDT.[44] Canada banned the use of DDT in 1970. Two years later, the Environmental Protection Agency (EPA) under the authorities granted by the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) banned most uses of DDT in 1972. It is important to note that DDT may still be used in other areas of the world including some within the peregrine's migratory range. *F. p. tundrius* was delisted from the endangered species list by the USFWS in 1984. In 1999, the same designation followed for *F. p. anatum*. The conservation status of the peregrine falcon in Canada varies from "No Status" to "Endangered."[73]

The monitoring of peregrine falcon populations was initiated by Colonel Meredith, who surveyed peregrine falcons on Padre Island, TX, from the 1940s through 1965, during their autumnal migration. Padre Island would become known as a key migratory route for peregrine during their southward autumn migration and the only known staging area for *F. p. tundrius* during their northward migration.[74] Earthspan, a nonprofit organization formed in 1994, continues its biomonitoring and conservation efforts through the Padre Island Peregrine Falcon Survey, performing surveys in the fall and spring of each year. To

accomplish these surveys, Earthspan works in collaboration with Peregrine Fund, Texas Parks and Wildlife Department, the US Geological Survey, USFWS, and a number of individuals and volunteers who perform the surveys.

Legislation

North American Falconer's Association and falconry regulations

Prior to the 1950s, regulations to monitor the use and possession of raptors for falconry were essentially nonexistent. Most people interested in falconry were biologists, ecologists, and other scientists concerned with the natural history of the raptors used in falconry.[43] Thus NAFA then became a voice and advocate for not only the practice of falconry but also the conservation of birds of prey.[43]

The Migratory Bird Treaty Act (16 U.S. Code 703–712, MBTA) was originally enacted in 1916 between the United States and Great Britain on behalf of Canada. It was signed into law in 1918, and upholding the treaty with Canada; the MBTA prohibits the take (including killing, capturing, selling, trading, and transport) of protected migratory bird species without prior authorization by the Department of Interior USFWS.[75] The MBTA implements four international conservation treaties that the United States entered into with Canada in 1916, Mexico in 1936, Japan in 1972, and Russia in 1976. The law has been amended with the signing of each treaty, as well as when any of the treaties were amended, such as with Mexico in 1972 and 1976, and Canada in 1995. In 1972, raptors were added to the list of birds granted federal protection by the annex of the US MBTA with Mexico. However, there were consequences for North American falconers and falconry as a result (see section on Operation Falcon).

With growing concerns over the protection and inclusion of all raptors under the MBTA in 1972, the enactment of the Endangered Species Act of 1973, and the earlier enacted Lacey Act of 1900, NAFA's initial efforts were to acquire legal recognition of falconry as a hunting sport at a state level.[44] However, NAFA ultimately directed its attention toward federal regulation of falconry and the USFWS, Department of the Interior. The first edition of the *Code of Federal Regulations* (CFR) was published in 1938. It is divided into 50 Titles that represent broad areas subject to federal regulation. The portion of the CFR that governs falconry standards and permitting is Title 50, Part 21 (50 CFR § 21.82).[76] While this system allows regulation of falconry at both the state and federal level, state regulations may be as stringent, or more stringent than federal requirements. Canada differs from the United States in that the guardianship of its natural resources is the responsibility of each province and not their federal government. Current regulations for each state and Canadian province are found on the NAFA's website (https://www.n-a-f-a.com).

Licensure and Regulations to Practice Falconry

United States

Persons interested in becoming a falconer often seek initial advice from their state or provincial wildlife agency or inquire with their local falconry organization. Often, the agency will send a packet of information regarding how to become a falconer, as well as state requirements, and some information for preparing for a falconry examination. The state agency or local organization may then direct them to seek the assistance of a falconer. A falconer, of general class or higher, may likely agree to sponsor the person, assist them through the application and licensing process, and acquisition of required equipment, as well as help them acquire and train their first raptor. The level of commitment by sponsors may vary.

Licensure to practice falconry in the United States requires the applicant to pass, with a score of 80% or better, a qualifying state examination. Similarly, an examination is also required in Canadian provinces. For example, Ontario requires Apprentices to take the Ontario Hawking Club's falconry examination. The examination evaluates the applicant's knowledge of natural history, managed care, falconry techniques and equipment, and laws and regulations governing the sport. Once passed, the individual is not required to take the examination again unless there is a prolonged lapse in their practice of falcon, and there is reciprocity between states should a falconer move from one state to another. If passed, the Apprentice falconer may pursue acquiring the necessary equipment (e.g., appropriate leather glove, jesses, anklets, swivels, leashes, scale, an appropriate perch for the species, water pan, and a mew), all with the help of their sponsor. North American falconers are also required to obtain general hunting licenses in addition to their falconry license to pursue game.

There are three classifications of falconers in the United States. Apprentice falconers, per most state regulations, must be at least 14 years of age and have the sponsorship and support of a General- or Master-level falconer. For those states that have essentially adopted the federal falconry regulations as their state regulations, the minimum age to practice falconry is 12, although this may still vary from state to state. The falconer must remain an Apprentice for at least 2 years, and some states may limit on the number of Apprentices a sponsor may have at one time. Historically, Apprentice falconers were only allowed one bird at any time and were required to trap and train either an American kestrel, a red-shouldered hawk *(Buteo lineatus)*, or a red-tail hawk. Apprentice falconers are not permitted to take an eyass raptor from the wild and may only replace one raptor per year. General falconers must have actively practiced falconry for at least 2 years and must be at least 16 years of age; however, age requirements may vary from state to state. Apprentice and General falconers who are less than 18 years of age must have a parent or legal guardian who is legally responsible for their activities. As with Apprentice falconers, there are possession limitations for General falconers that limit possession to no more than two raptors, or replacement of two raptors per year. In addition, General falconers may not hold, keep, or transport threatened or endangered raptor species. Master falconers have been practicing falconer for at least 5 years at the level of General. Federal falconry regulations state that Master falconers may possess no more than five wild raptors, including golden eagles, and replace only two per year. Master falconers may possess any number of captive-bred raptors that are trained in the pursuit of wild game. Unless authorized by the USFWS, falconers may not possess any raptor species listed as threatened or endangered, and US falconers may not take or possess a bald eagle *(Haliaeetus leucocephalus)* for falconry. In the United States, falconers may trap passage (hatch year) raptors from the wild for use in falconry; however, exceptions exist for species such

as great horned owls *(Bubo virginianus)* and American kestrels, which may also be taken as adults at specific times during the year. Passage take of raptors is relatively new in some Canadian provinces. In the United States, all acquisitions, transfer (gift, sale, or loan), loss, or death of a raptor used for falconry are submitted to the USFWS, historically by paper and now electronically, through a Federal Fish and Wildlife Permit Application Form (Form 3-186a—Migratory Bird Acquisition and Disposition form).

Canada

In Canada, provinces differ on the minimum age requirement to practice falconry. For example, in Ontario, a person must be at least 15 years of age to practice falconer, while Saskatchewan requires falconers to be at least 12 years of age. In contrast to falconry levels in the United States, there appears to be no designation of Master falconer; instead only Apprentice and General falconers are recognized in the provinces. The apprenticeship must be sponsored by someone who has been a General falconer for a minimum of 5 years and lasts for at least 15 months, which includes two autumn hunting seasons. In Canada, reporting of acquisitions, transfers, loss, or death of a raptor used in falconry varies between provinces. In most provinces, reports are provided when they occur. In Ontario, falconers record these in a logbook and report this information once a year to authorities; however, the logbook is subject to inspection at any time.

Mexico

Wildlife management and regulations in Mexico have undergone significant and rapid changes. However, since 2001 wildlife management responsibilities have fallen under the Ministry of the Environment and Natural Resources (Secretaría de Medio Ambiente y Recursos Naturales [SEMARNAT]). In 1993, Raul Ducoing presented a proposal for falconry regulations in Mexico to the Mexican government, and this became a Norma Oficial Mexicana (NOM) for falconry, or compulsory standards and regulations. Unfortunately, the Chief Executive Officer of SEMARNAT was assassinated and the regulations were put on hold (Raul Ducoing, personal communication, 2020).

In 1998, a new initiative from Mexican wildlife authorities, including SEMARNAT and Procuraduría Federal de Protección al Ambiente (PROFEPA), was designed to govern falconry activities in Mexico. SEMARNAT develops and implements national policy on protection, restoration, and conservation of natural resources and provides permit guidance for Mexican falconers. PROFEPA provides law enforcement guidance and monitoring for illegal hunting activities. Currently, there are little to no regulations that govern falconry and very little interest from authorities or traction to push for them in Mexico.

At present, falconers in Mexico are not allowed to trap raptors from the wild as in other areas of North America. From 2005 to the present, only captive-bred or imported raptors are allowed for falconry, and importation of raptors into Mexico for falconry is difficult. Currently, Mexican falconers also have no regulations or requirements for mentorship of new falconers, or for how birds are housed or trained. Most beginner falconers are directed to hunt with Harris hawks, rather than kestrels or red-tailed hawks, as is in other areas of North America (Raul Ducoing, personal communication, 2020). Most experienced falconers in Mexico are training and hunting with Harris hawks, Cooper's hawks, and peregrine falcons (Raul Ducoing, personal communication, 2020).

Operation Falcon

No report of falconry in North America would be complete without including some discussion of Operation Falcon, an undercover operation conducted jointly by the USFWS Department of the Interior and the Canadian Department of Justice/Canadian Wildlife Service that concluded in 1984. During the 1970s, USFWS and the Canadian Wildlife Service began collecting intelligence data and became convinced that there was an illegal, multimillion-dollar, black market, international trade of valuable falcons (peregrine falcons and gyrfalcons) and their eggs from North America to Europe and the Middle East. The undercover phase of the operation culminated on June 29, 1984, and 9:00 a.m. Eastern Standard Time marked the moment USFWS and state agents descended on North American falconers executing searches, arrests, and seizures of more than 100 hawks and falcons.[44,77] Their primary targets were falconers and raptor breeders, mainly peregrine falcon breeders.[77] As per a news release from the US Department of the Interior, Operation Falcon lasted approximately 3 years, resulting in 30 arrests and estimates of as many as 400 birds illegally taken from the wild.[78] Tantamount to the Department of the Interior's news release, the National Audubon Society provided a similar release espousing the "success" of the Department of the Interior's Operation and even estimating the number of arrests to be 50 individuals with 500 birds illegally smuggled.[77,78] Ultimately, USFWS failed to prove the existence of substantial, illicit, black market trafficking of falcons in the United States.[77] Congress was informed of the abuses in Operation Falcon through a series of hearings culminating in a hearing before the House Subcommittee on Fisheries and Wildlife Conservation and the Endangered Species Act.[77] During this hearing, the USFWS Division of Law Enforcement was subject to criticism by the subcommittee members.[77] Both USFWS Law Enforcement and the National Audubon Society suffered embarrassment, and their actions gained distrust from North American falconers.[44] John Jeffery McPartlin, a falconer convicted of violating the Lacey Act, served as a sting operator and informant for the USFWS.[44,77] Operation Falcon was the subject of *The Pilgrim and the Cowboy*, which provides a good summation of this challenging time in falconry.[79]

FALCONRY IN NORTH AMERICA—THE PRESENT

In North America, falconry is the most highly regulated field sport, even compared to other methods of hunting with guns. In the United States, falconry is legal in all states except Hawaii and the District of Columbia. In Canada, falconry is not legal in every province.

Legal falconry is practiced in British Columbia, Alberta, Saskatchewan, Manitoba, Ontario, and Quebec. The New Brunswick Falconry and Austringer Association appear to be active; however, falconry appears to be illegal in this province.

The USFWS estimates approximately 6200 currently permitted falconers in the United States, approximately 65% are active with raptors on their permits. Current NAFA membership

is approximately 2000 members, 200 to 300 of which are international members. Women represent approximately 18% to 20% of membership, and the numbers are growing (Nicolle Sheldon, personal communication, 2020). There are significant numbers of underrepresented minority falconers in North America, and those numbers are growing as well; however, there is little data available to provide any statistical conclusions (Sheldon Nicolle, personal communication, 2020). In Canada, the number of falconers is considerably less than in the United States and is estimated to be between 400 and 500, with 50% or more licensed in Ontario. While Ontario has the largest number of falconers and perhaps the largest provincial club, The Saskatchewan Falconry Association is reportedly the oldest, continuously operating falconry association in North America. Significant numbers of falconers are also present in Quebec and Alberta, while Saskatchewan, Manitoba, and the eastern provinces have active but small falconry communities (Martin Geleynse, personal communication, 2020). While Mexico has approximately seven to eight falconry clubs or groups with around 950 falconers, there are 150 falconers who are actively practicing the sport, and of those, approximately 35 are Master falconers/professional falconers (Raul Ducoing, personal communication, 2020). The remainder of the 950 falconers are considered falconry enthusiasts and may practice the sport then are quickly out of falconry. Women represent approximately 0.05% of practicing falconers in Mexico (Raul Ducoing, personal communication, 2020).

Since 1962, NAFA has held field meets for its membership. These meets, which often occur over the Thanksgiving holiday, provide falconers the opportunity to share their experiences, learn from other falconers, and disseminate knowledge.

Since its inception, and for quite some time, NAFA has been the representative voice of falconers in North America and provided notable publications in the form of the annual NAFA journal and the *Hawk Chalk*. In the fall of 1995, the first volume of *American Falconry Magazine* was published. This journal is devoted to the sport of falconry, produced by practicing falconers, and highlights news and issues important to falconers including legislative information, training techniques, dogs used in falconry, falconry equipment, and veterinary care. Initially, NAFA only allowed US and Canadian falconers as members. However, in 1999, an amendment was made to NAFA's Constitution and Bylaws that allowed Mexican falconers over the age of 18 to join NAFA, thereby allowing Mexico to become a member of NAFA.

While NAFA had been the main voice of North American falconers since its inception, in 2002, the nonprofit American Falconry Conservancy (AFC) was conceived. The AFC, which also included many NAFA members, had differing views regarding falconry regulations and wild take of raptors for falconry than NAFA. AFC's mission is to protect and preserve falconry in the United States for future generations by protecting the falconer's rights as legitimate sportsmen and conservationists.[80] This would be accomplished by pursuing the broadest liberties possible that are not in conflict with legitimate conservation efforts based on sound biological and legal reasoning.[80]

Landscape

Falconry in North America is unique given the diversity of private and public landscapes on which to hunt, the diversity of raptor species used (hawks, eagles, and falcons), and the diversity of quarries available for falconers to pursue. As the third largest continent, geography varies tremendously across the United States and Canada, ranging from mountainous ranges, expansive prairies and steppes, tundra, dense forests, deserts, wetlands, and lowlands.

Raptors

Due to the dramatic differences in terrain across the United States, falconers attempt to choose the raptor species most suitable for the terrain and available quarry. As varied as the landscapes are, so are the raptors commonly used in falconry in North America. These range from the diminutive sharp-shinned hawk or American kestrel to the formidable golden eagle. Sources of raptors include captive-bred species as well as those taken as eyass or passage birds from the wild, and there are a number of raptor breeders across North America. NAFA provides a list of breeders that includes members of the North American Raptor Breeders Association (NARBA). Until recently, Canadian falconers were not allowed wild take of raptors for falconry, and regulations vary between provinces. Captive-bred birds may either be imprinted or trained when they are older.

Red-tailed hawk

Found throughout continental North America, except northeastern Canada, there are approximately 14 recognized subspecies of this large *Buteo*. Although most red-tailed hawks look similar, the Krider's *(B. j. kriderii)* is a light-colored morph of the eastern red-tailed hawk *(B. j. borealis)*, and the Harlan's *(B. j. harlani)* may be blackish-brown in color, or may also demonstrate light-colored morphs. Red-tailed hawks are one of the more popular raptors used in falconry in the United States and are often the first raptor trained by many falconers when they start. Not surprisingly, experienced falconers also choose to use red-tailed hawks, especially if quarries (e.g., squirrels) are the most accessible game in their area. Even though this is a larger raptor, it is very effective, efficient, and versatile at catching a variety of game including small mammals, waterfowl, upland game birds, and jackrabbits. Red-tailed hawks are often wild caught by falconers, as (mal)imprinted individuals may become quite aggressive toward the falconer. Surprisingly, red-tailed hawks are not commonly used in falconry in Mexico. Hybridization of red-tailed hawks with other species such as ferruginous hawks and Harris hawks has been created. These hybrids have been produced but are uncommon in the United States (see also section on Falconry in the UK—The Present). Red-tailed hawks weigh between 710 to 1550 g.[81]

Ferruginous hawk

The ferruginous hawk is the largest *Buteo* in North America. Powerfully built with a rather large gape, this hawk possesses considerable grip strength and is able to dismember its prey, swallowing large portions rather quickly. Feathered tarsi are a distinguishing characteristic of this species. Similar to red-tailed hawks, both light and dark morphs occur. Its southern range is primarily the arid and prairie regions of the southwestern United States, extending into Mexico. Its northernmost range is southern Canada, primarily Alberta and Saskatchewan. This hawk may be challenging and generally not for the novice falconer. The weight range for male and female ferruginous hawk is 980 to 2030 g.[81]

Harris's hawk

The Harris's hawk deserves a special mention as no other species of raptor has revolutionized falconry in North America and several regions around the world, compared to this extremely versatile hawk.[82] This hawk is the only member of the genus *Parabuteo*, and two subspecies of Harris's hawks are recognized. The northern *P. u. harrisi* is found in the southwestern United States, Mexico, Central America, and into South America along the western slope of the Andes from western Colombia to northwestern Peru.[81] The southern *P. u. unicinctus* is only found in South America, and its range extends from Colombia through Chile and Argentina, except for the western Pacific slope from the Panama-Colombia border, and south through Peru. The social nature of Harris's hawks has been well studied. In the wild, these hawks may hunt collaboratively and live in extended family groups. In falconry, the Harris's hawk's social hunting style allows multiple falconers and multiple hawks to hunt simultaneously. Its easy temperament, versatility, intelligence, flexibility, adaptability to hunt in a variety of conditions, and social interactions allow a comradery between falconers that is not seen with other raptors (Figure 55.21). Well suited for warm and hot climates, the one drawback, if there is any, is that this hawk does not do well in colder climates, and frostbite can be a common problem in colder climates. This hawk is extremely popular in Mexico and is the most common raptor used (see also section on Falconry in the UK—The Present). Geographic variation exists between Harris's hawks from different regions and subspecies. Reportedly, the weight range for *P. u. harrisi* can vary tremendously and range from 550 to 829 g for males to 825 to 1633 g for females,[82] but most adult females average around 1000 g. *P. u. unicinctus* are smaller.

Currently, Harris's hawks are one of the most common hawks bred and flown in falconry. In 1999, the Baywing Database was created by falconer Toby Bradshaw to allow for a global registry of captive-bred Harris's hawks (https://baywingdatabase.com/). The purpose of the Baywing Database is to collect, store, analyze, and distribute information on Harris's hawks used for falconry, and it allows falconers to register their hawk(s), generate a pedigree for any registered hawk, find a hawk's relatives, or even run a trial mating.[83]

FIGURE 55.21 "Hannibal" and "Moe" represent two extraordinary descendants of the Harris's hawks *(Parabuteo unicinctus)* "Malcom" and "White Wing"; their bloodlines are well known among North American falconers and Harris's hawk breeders. Their speed, versatility, persistence when pursuing game, sociality, ease of handling, intelligence, and impressive game records are attributed to selective breeding, parent rearing, socialization conditioning, and being provided hunting areas with abundant game. (Photo courtesy Jennifer O. Coulson, used with permission.)

Accipiters

See also the section on Falconry in the UK—The Present.

Accipiters are common in North American falconry and are represented by the northern goshawk, the Cooper's hawk, and the sharp-shinned hawk. Accipiters have the reputation of being high-strung, temperamental, and sometimes aggressive toward the falconer, requiring patience in handling. Accipiters may be taken from the wild as eyass and passage birds, although most falconers take them at a young age, preferring to imprint them.[84,85]

Northern goshawk. See also sections on Falconry in Asia—The Present and Falconry in Europe—The Present.

Formerly classified as *Accipiter gentilis* spp., the northern goshawk has recently been divided into two species, the American goshawk (*Accipiter atricapillus* spp.) and the Eurasian goshawk (*Accipiter gentilis* spp.).[86–88] *A. atricapillus atricapillus* are found throughout North America, except for the west and extreme southwest. *A. a. laingi* are found on Vancouver and Queen Charlotte Islands off the coast of British Columbia, and *A. a. apache* range from southern Arizona and New Mexico into Mexico.[81,89,90] Goshawks are highly prized in falconry for their speed, agility, and versatility. The American goshawks differ from their Eurasian counterparts in that their color is darker dorsally and there is fine dark barring ventrally. As they mature, their iris progresses from gray to yellow, then orange, and finally red as they reach 4 to 5 years of age; Eurasian goshawks retain yellow-orange irises as they mature. A number of North American falconers prefer to hunt with the somewhat larger Eurasian species of goshawk such as the Russian or Siberian goshawk (*A. g. albidus*; Figure 55.22) or Finnish goshawks *(A. g. gentilis)*. Weight range for *A. a. atricapillus* ranges from 677 to 1014 g for males and 758 to 1214 g for females.[81]

Cooper's hawk. This hawk is mid-sized between the goshawk and sharp-shinned hawks. Cooper's hawks will catch a variety of game including small birds, mammals, and even larger-winged quarry such as small ducks. However, similar to goshawks they can be quite temperamental and aggressive toward the falconer when taken as an eyass. Techniques for raising, training, and hunting with imprint Cooper's hawks are well described.[84] Cooper's hawks are one of the more commonly used species in Mexico. Weights range from 302 to 402 g for male and 479 to 678 g for female Cooper's hawks.[81]

Sharp-shinned hawk. Sharp-shinned hawks, or "sharpies" as they are often called, are the smallest of the North American accipiters, yet they have the same drive and determination as seen in their larger cousins. Similar to the other North American accipiters, most falconers will choose to imprint this hawk and use it to pursue small-winged quarry. Weights range from 87 to 114 g for male and 150 to 218 g for female sharp-shinned hawks.[81]

FIGURE 55.22 Larger goshawk species, such as this Siberian goshawk *(A. g. albidus)*, are becoming more popular among North American goshawk enthusiasts. (Photo courtesy Darryl Perkins, used with permission.)

Falcons

Both large and small falcons are very popular among North American falconers, and many of the same falcons and hybrid falcons flown in other regions of the world are used to take quarry in North America (see also section on Falconry in the Middle East—The Present). Unique to North America are the American kestrel, prairie falcon, and the aplomado falcon. Smaller species such as merlins are generally flown from the glove in direct pursuit of prey and occasionally from a modest pitch. Larger species are generally flown from higher pitches to catch feathered game, although some falconers will also use them with sight hounds, in particular lurchers, to catch ground quarry such as jackrabbits. Peregrine falcons are the most popular falcon flown in Mexico, but aplomado falcons are gaining favor.

American kestrel. The American kestrel is the smallest and, perhaps, the most colorful falcon in North America and has a wide range of distribution across the continent. Their colorful plumage is only rivaled by the aplomado falcon, of which there are several subspecies (*A. femoralis* spp.). American kestrels are sexually dimorphic. Males possess a blue-gray crown with a reddish brown nape and back that is barred. The dorsal aspect of the wings is also blue-gray in color, and the dorsal aspect of the primaries is black with white spots. The tail is also reddish brown, with a usually white tip and a black sub-terminal band. Female kestrels have a similar coloration on the head, but the back and dorsal aspect of the wings and tail are reddish brown and heavily barred. Both male and female American kestrels have a pronounced malar stripe on the side of the head. Even with its small stature, the American kestrel is a fantastic falconry raptor and is one alternative for falconers to train when they begin their falconry journey. Used to hunt primarily small birds (sparrow, starlings) and rodents, the American kestrel is well respected in falconry. American kestrels are widely distributed across North America and are able to thrive in a variety of habitats, including urban and suburban locations. Males are slightly smaller than females. American kestrels are generally 97 to 150 g in body weight.[81]

Prairie falcon. The prairie falcon is a large falcon and is similar in size to the peregrine falcon. It inhabits the more arid and open regions west of the Mississippi River, and its range extends from central Mexico northward to southern British Columbia, Alberta, Saskatchewan, and Manitoba. Free-ranging prairie falcons are capable of taking a wide variety of prey, from small passerines to black-tailed jackrabbits *(Lepus californicus)*. Also requiring patience in handling, the prairie falcon is known for its tenacity and forceful airstrikes that can incapacitate, if not kill, its intended prey from a pitch. Prairie falcons generally weigh between 420 and 1100 g.[81]

Aplomado falcon. The range of the aplomado falcon extends from southern Texas well into Central and South America. Once common in the southwest United States, this falcon is considered endangered but is now being reintroduced in south Texas. Aplomado falcons are unique in their hunting habits. While most large falcons prefer not to pursue ground quarry, the aplomado is used in falconry to pursue avian and small mammalian quarry including cottontail rabbits (*Sylvilagus* spp.). Aplomado falcons generally weigh between 208 and 460 g.[81]

Merlin. The merlin is a small falcon but larger than the American kestrel. Merlins have a large distribution including breeding and wintering areas in North America, Central and northern South America, the Caribbean, as well as North Africa and Eurasia. There are three distinct subspecies in North America including *Falco columbarius columbarius* (i.e., Taiga or tundra merlin) that breed in the boreal forest from Alaska to Newfoundland and winter in the southern United States and southward; *F. c. richardsonii* (i.e., prairie merlin) breed on the northern Great Plains and winter there and southward; and *F. c. suckleyi* (i.e., black merlin) which are resident in the wet temperate forests of coastal British Columbia and Washington, with some birds moving southward in winter.[81] A number of North American falconers enjoy pursuing small avian species with merlins. Merlins generally weigh between 129 and 236 g.[81]

Eagles

Eagle falconry is relatively new to North America and practiced by a relatively small subset of falconers. The golden eagle is the most common species used, although there are some falconers that use nonindigenous species to catch game including the African crowned eagle, the ornate hawk-eagle, and others. Jackrabbits, both black-tailed and white-tailed *(Lepus townsendii)*, and larger quarry, such as coyotes *(Canis latrans)*, are common prey for eagles (Figure 55.23). Eagles are commonly hunted either from a soar while above the falconer or directly from the fist. Golden eagles generally weigh between 3 and 6.4 kg.[81] Falconers in the United States are not permitted to take and possess a bald eagle for falconry.

FIGURE 55.23 A golden eagle (*Aquila chrysaetos*) is about to come to grips with a black-tailed jackrabbit. (Photo courtesy © Aaron Allred.)

Osprey

Ospreys are one of the most widely distributed raptors in the world, yet descriptions of their use in falconry in North America are extremely rare. However, most recently, a more detailed description of husbandry and falconry training techniques designed for ospreys became available with the publication of *Ospreys in Falconry: Lessons Learned* and an online blog that further details the authors' experience while training an osprey available at https://ospreyfalconry.com.[91] Admittedly, there is still a lot to learn about this highly specialized raptor and its future applications in falconry.

Equipment and Training

Facilities

Facility requirements vary in North America; however, in general, most falconers must possess necessary facilities and equipment (see section on Falconry in Mexico and Table 55.1) before obtaining a raptor for falconry. Most falconers maintain their raptors in an outdoor aviary known as a mew. Requirements for mew design may vary between state and province and should allow the raptor to easily extend its wings, should provide appropriately sized perches for the species, allow easy access to water, should have at least one window with vertical bars, and protect the raptor from environmental extremes and potential predators. The roof of the mew may be solid, netting, or barred to allow varying amounts of exposure to the environment while also allowing the raptor full protection. Most raptors are housed individually in mews during the hunting season, although some species may be housed communally during the off-season or if used for breeding.

A weathering area is an outdoor facility that may be attached to or separate from the mews. This structure consists of a fenced area that may be covered by a solid roof, netting, or wire. Here the raptor is given monitored exposure to the elements. Raptors are generally tethered to a perch, with access to water, while in a weathering yard. Outdoor perches of appropriate design for a falcon, hawk, or eagle are necessary.

Equipment

This list of necessary falconry equipment includes a glove (gauntlet) of appropriate size and thickness for the raptor, at least one pair of jesses made of a pliable leather or synthetic material, at least one leash of appropriate length and thickness for the species being used to hunt, at least one swivel for use with the leash and jesses, a bath container for the raptor to bathe and drink, and a scale to weigh the raptor. Most, if not all, of the equipment can be made by the falconer, usually from leather. Other equipment such as bells, which are used to help locate the raptor when near the falcon, and telemetry, a system that helps locate a lost or difficult-to-locate raptor, are extremely important. In some regions of North America, the United States, for example, hybrid falcons are required to have two transmitters when flown free. Conversely, falconers in Mexico are not required to use a transmitter for any falconry bird. Falconry telemetry consists of a transmitter that is attached to the raptor and a receiver that receives the transmitter signal. Commonly used transmitters are available in very high frequency (VHF) or ultrahigh-frequency (UHF). However, many falconers are gravitating toward the use of a more efficient way to track and recover raptors with the use of lightweight GPS transmitters that use a satellite navigation system to provide the location of raptor even up to 100 miles away from the falconer. While other GPS systems are available, the most popular system in North America, as well as other parts of the world including Europe and the Middle East, is the Marshal GPS system (Marshall Radio Telemetry, Salt Lake City, UT; Marshallradio.com). In conjunction with a smartphone, this GPS system can provide real-time location of the raptor, location of the falconer, and additional parameters such as altitude, speed, climbing rate, temperature, and distance traveled by the raptors.

Feeding and weight management

Training a raptor for falconry is a time-consuming process. Food is introduced to the raptor early in the training process, either on the glove when it is being manned, on the lure, or given directly to the raptor. Manning occurs when the raptor is in close proximity to the falconer or on the falconer's glove, and the fear of the falconer is neutralized and diminished. Traditionally, weight management and controlling the amount of food offered have been used to motivate raptors to respond to the falconer's call and pursue prey for the falconer. However, falconers are now pushing the envelope when it comes to behavioral modification and using various behavior strategies to reinforce wanted behavior, rather than always relying on maintaining a raptor's weight within a specific range. Some initial weight adjustment may be necessary early in the manning and training process, and it is important to use the scale to track the raptors weight at all stages of manning, training, and hunting; however, food deprivation to dramatically reduce the weight of the raptors is discouraged. Training is different from manning; where the latter is a course of action to get the raptor acclimated and not fearful of the presence of the falconer, training is teaching the raptor what the falconer expects in order to become a successful hunting team and the raptor accepts the falconer as a hunting partner.

Training

All of the techniques described earlier (see section on Falconry in the Middle East—The Present) for training are also used by North American falconers including lures, kites, balloons (helium), fixed-wing remote-controlled airplanes, and drones. Lures are an indispensable piece of equipment for any falconer. Classically, lures are a leather sack in which weight is added, although lures can take any form, from a prey item to a plastic bag. Lures are introduced during the training process and a variable-sized piece of food is attached to it. The raptor quickly learns that it will be rewarded when it comes to the lure, thus making it indispensable in calling a raptor back to the falconer, even from great distances or heights.

Similar to the practice of falconry in other regions of the world, kites, balloons, and fixed-wing remote-controlled airplanes can be used as tools to condition a falcon or hawk, or as a training tool to help the falcon develop a higher pitch above the falconer. For the latter, drones, kites, and balloons excel. These tools are not necessary to train a falcon; however, they can be quite useful. Drones appear to be more popular than balloons or kites, as they do not require maintaining a tank of helium or depend on wind speeds, respectively. Not surprisingly, recommendations for training a falcon with a drone vary between falconers; however, one author provides a description of the technique including types of drones, necessary equipment (e.g., parachutes and bait release systems), and training technique.[92] In short, a falcon or hawk is allowed to grab a bait or lure suspended beneath the drone by a bait release system, which holds a parachute attached to the lure. The distance of the lure or bait from the drone and the distance from the parachute to the lure vary depending on the comfort level of the raptor when approaching the drone. The distance from the drone to the lure may be as much as 20 to 25 feet. Once the falcon climbs to the drone and grabs the bait or lure, a parachute is deployed and the raptors can descend to the ground. Falcons may drift some distance from where they took the bait/lure depending on the wind speeds and the height of the drone. When using a kite or balloon, the bait is suspended in a similar fashion but without the parachute. The bait line is instead attached to the kite or balloon line, and the falcon descends to the base of the line. Falconers in more confined areas must take into consideration the amount of open space available, surrounding trees, and manmade structures (telephone poles and lines) when drone training a falcon. In the United States, the height of the drone is limited by Federal Aviation Administration (FAA) rules for small, unmanned aircraft.

Quarry

Along with its diversity of habitat, North America likely has the greatest variability of game available to falconers. The term "game" is loosely applied to any species pursued by falconers and may also include species not generally considered food for the table. For example, falconers that hunt with American kestrels, merlins, sharp-shinned hawks, and other smaller raptors often opt to pursue English or house sparrows, rock pigeons, mourning doves *(Zenaida macroura)*, starlings, or small rodents. These are offered as food to these smaller raptors or even used to feed larger raptor species. The most common species hunted fall under the categories of small game such as squirrels, cottontail rabbits, jackrabbits or hares; upland game birds such as common pheasants *(Phasianus colchicus)*, northern bobwhite quail *(Calinus virginianus virginianus)*, Gambel's quail *(Callipepla gambelii)*, California quail *(Callipepla californica)*, sharp-tailed grouse *(Tympanuchus phasianellus)*, greater prairie chicken *(Tympanuchus cupido)*, sage grouse *(Centrocercus urophasianus)*; numerous migratory species such as waterfowl (Figure 55.24); and even fur bearers.

Most falconers try to match the raptor they use with the game available in their region. However, falconers commonly travel great distances to hunt game not readily available to them near their home. Falconers that hunt ground quarry are often colloquially referred to as "dirt hawkers," while those who pursue quarry with falcons are called "longwingers"; however, they are not mutually exclusive. Some longwingers

FIGURE 55.24 (A) A falconer prepares to release his tiercel gyr × peregrine falcon hybrid for a flight on ducks. (B) One author's (M.P.J.) tiercel gyr × peregrine on a drake mallard duck. Falcons dispatch their prey quickly by severing vital structures such as the spinal cord, jugular veins, and carotid arteries. (A, Photo courtesy Shawn Hayes, used with permission. B, Photo courtesy Michael P. Jones.)

will pursue ground quarry such as jackrabbits with falcons, and "dirt hawkers" will pursue quarries traditionally reserved for falcons with various species of hawks. The term austringer has been used to describe falconers who train and hunt with accipiters, more specifically goshawks, and the term is also sometimes applied to falconers who hunt with eagles. Regardless of the quarry, North American falconers adhere to the hunting season, permit, and bag and possession limit regulations as determined by each state, tribal or territory, province, or federal regulations. Some special consideration is given to falconers in the form of extended seasons. For example, while duck season for gun hunters in Tennessee may extend into the last week in January, falconers may hunt through the end of February as part of an extended falconry duck season in the Mississippi Flyway as falconry has no impact on game species numbers. Should the falconer's bird accidentally catch a protected species, either during the closed or open hunting season, the raptor is allowed to consume the prey, but the falconer is not allowed to remove the prey's carcass from the field and must "let it lay." Some states or provinces may require reporting the date and location of incidental take of endangered or protected species.

Dogs

Dogs are often an instrumental part of the falconry team. Falconers pursuing upland game with falcons often chose pointing or versatile hunting dog breeds (e.g., English Pointers, English Setters, Spaniels, Vizslas, German Shorthaired Pointers, etc.; see also section on Falconry in Europe—The Present), while those pursuing ground quarry and squirrels may choose to use Dachshunds, various terrier breeds (e.g., Jack Russell terriers, Decker terriers, Jagdterriers, etc.), beagles, Feist and Cur breeds, as well as sight hounds or lurchers (sight hounds crossed with a working dog breed [terrier, herding breed, or scent hound]). Sight hounds such as greyhounds and lurchers are used to pursue prey such as jackrabbits under falcons, hawks, or eagles.

Falconry-Based Bird Abatement and Pest Control

See also section on Falconry in the UK—The Present.

While not considered falconry in the truest sense, a number of falconers in North America use raptors to control bird species considered pest or nuisance birds (e.g., starlings and pigeons) to reduce lost crop loss, property damage, public health concerns, and reduce airstrikes by bird at airports.

Innovation

Free of the constraints of long-established falconry traditions, North American falconers have contributed significantly to the practice of falconry through innovation and advancement of the practice of falconry.[44] These innovations include (1) establishing captive breeding methods to facilitate the production of purebred and hybrid raptors for use in falconry; (2) the development of radio telemetry systems for location and recovery of lost hawks and falcons; (3) the development of the American hood, which uses a lighter leather and demonstrates exceptional hood-making technique in delivering a hood with a beak-opening that contours to the falcon's head; (4) developing a cure for frounce (trichomoniasis); and (5) introducing the red-tailed hawk and Harris's hawk to international falconry (Kent Carnie, personal communication, 2020).[44]

FALCONRY IN NORTH AMERICA—THE FUTURE

The future of falconry looks promising, although varying degrees of optimism, pessimism, and skepticism exist. Some falconers see the eminent loss of falconry as a sport, but most falconers agree that there will be challenges to overcome. Likely, the single greatest challenge to falconry in North America will be the ever-increasing expansion of intensive agricultural practices, especially those that employ the use of pesticides and other chemicals harmful to the environment. Falconers often see firsthand the rapid loss of habitat and suitable places to train and hunt with their raptors. Falconers often reminisce of their favorite hunting areas that were once rich in game but are now lost to intensive agriculture, housing developments, and shopping malls. Habitat loss combined with anthropogenic impact and its effect on the environment, ecosystems, and biodiversity (e.g., climate change) may continue to result in declining game populations (e.g., multiple species of cottontail rabbits, snowshoe hares *[Lepus americanus]*, multiple species of quail such as the California quail, sage grouse, etc.), and game that is increasingly harder to find. Some falconers in North America believe that the future of the sport is bleak and suggest that younger generations practicing today may see the end of falconry as a field sport. Perhaps the future of falconry for some who have lost habitat and game may be the pursuit of micro-falconry, the flying of small raptors (e.g., sharp-shinned hawks, merlins, and kestrels) in a way that does not require expansive farm or woodlands to practice the sport.

Another significant challenge to the future of falconry in North America is regulations that may create an environment of mistrust between falconers and various regulatory agencies. In fact a number of falconers believe the sport should not be constrained by regulations at all. Operation Falcon represented a dark time for North American falconers. While its claims were unsubstantiated, it cast a negative light on falconry, and falconers became reluctant to openly share details of the sport in order to protect it from those that would not appreciate its value.

In 2008, the USFWS announced a major overhaul of its falconry regulations that went into effect on January 1, 2014. First, the new falconry regulations would eliminate the need for dual state/federal permit, and the USFWS would approve falconry regulations that "reflect current practices in the traditional use of raptors for sport hunting." These regulations would be administered under state, tribal, or territorial laws and regulations, with the understanding that state, tribal, or territorial laws may be more restrictive, but not less restrictive, than federal regulations. Second, USFWS established an electronic reporting system to record acquisition, transfer, or loss of raptors used for falconry. Third, the new regulations allow experienced falconers to assist federal and state-permitted wildlife rehabilitators with conditioning and release of raptors back to the wild. The Bald and Golden Eagle Protection Act, which was originally enacted to protect the bald eagle, then amended in 1962 to include golden eagles, regulates the taking, possession, and transport of eagles or their parts (inactive

or active nests, egg, feathers, blood, etc.). In part, it also provides regulations for the take and use of golden eagles for falconry in the United States.

Falconry, at best, is a fringe sport when compared to other hunting and fishing activities. Overall, members of the public are aware of the sport from something they have seen, read, or seen on social media. Even those aware of the sport, unless they know a falconer, have little understanding of the day-to-day responsibilities needed to keep, train, and hunt with raptors. Perhaps the opinion of the public is good, yet falconers must still protect and defend their passion from antihunting, animal rights organizations.

Falconers, at their core, are really conservationists practicing an ancient and highly participatory form of bird watching. For falconry to move forward, it will be necessary for NAFA, AFC, and each state's falconry association to continue their strong support of conservation and conservation efforts, to cultivate partnerships and relationships, to engage and educate the public, as well as mend fractured relationships with regulatory agencies/agents. For this "way of life" to flourish in today's society, public education must be built into our activities so that transparency rather than traditional stealth mode becomes the norm (Dr. Dave Mcruer, personal communication, 2020).

Finally, encouraging and supporting diversity and inclusion should be a driving force for falconry. Underrepresented minorities (URM) are becoming increasingly interested in falconry, and the numbers of falconers in this demographic are increasing. Unfortunately, national and falconry organizations have not historically collected demographic data regarding falconers who are members of URM groups or other demographics. Women are a significant and increasing percentage of the total numbers of falconers in NAFA, representing around 11% in the United States (Figure 55.25). For comparison, approximately 27% of members of the Ontario Hawking Club are women, and approximately 50% or more of the Québec Falconry Association's members are women (Martin Geleynse, personal communication, 2020). The increased knowledge, perspectives, insights, and talents that diversity would bring to national and state organizations and falconry would increase their strength, flexibility, adaptability, innovation, problem-solving, and ultimately performance as an organization and group.

FALCONRY IN CENTRAL AND SOUTH AMERICA—THE PAST

Falconry is practiced in many Central and South American countries today, using a wide variety of native raptor species to pursue a broad range of quarry in a diverse array of habitats. South American countries that currently have active falconry clubs include Argentina, Brazil, Chile, Columbia, Cuba, Ecuador, El Salvador, Paraguay, Peru, Uruguay, and Venezuela. While the earliest records of falconry in the "New World" arise quite early, it appears that falconry died out sometime in the 17th century until a revival in the mid to late 20th century in most of these countries.

The early historical record for falconry in the Americas is somewhat scant. There is no firm evidence that falconry was practiced prior to the arrival of European explorers.[44] When Columbus arrived in the Americas in 1492, hawk bells intended for trade with locals were included among the cargo in his ships (See section on Falconry in Mexico for historical perspective).[93]

In the colonial period, much of South America was originally under Spanish control as part of the viceroyalty of Peru, founded in 1543. This vast viceroyalty initially stretched from modern-day Panama in the north to Chile and Argentina in the south. To the east was the Portuguese colony of Brazil. Garcilaso de la Vega (1539–1616) describes falconry in two different passages in his Comentarios Reales. In the first, he describes soldiers traveling with slow-moving llama caravans, taking both dogs and hawks with them to hunt during the day. A few pages later, he further describes a man from Seville who attempted to train a dark-colored falcon that resembled a "nebli"; however, he was never able to successfully take quarry with it.[94] The first illustration of a falconer in South America is a native person employed as a falconer, with hawk in hand and two dogs, in a manuscript by Guzman Pomo de Ayala (1615).[95] In a book entitled *Histórica Relación del Reino de Chile y de las Misiones y Ministerios que Ejercita en la Compañía de Jesús*, Alonso de Ovalle described the use of casts of trained falcons for hunting southern lapwings *(Vanellus chilensis)*.[96]

Further north, the viceroyalty of Spain encompassed a large area of territory extending from the southwestern United States, Mexico, Central America, and Florida. The second viceroy of Spain, Luís de Velasco, who ruled from 1550 to 1564, possessed an extremely tame falcon that was celebrated to ride upon his fist unhooded. Additionally, he kept several different species of falcons.[44] His son, Luís de Velasco II, who spent time as both viceroy of New Spain and Peru, employed a royal falconer to care for his birds.[44]

There was a great demand for hawks from the New World in the European courts (see also section on Falconry in Europe—The Past). As early as 1494, King Ferdinand II sent

a letter to Christopher Columbus ordering him to bring back as many falcons as possible to Spain.[63] In 1501, an official Royal Falcon Catcher of the Indies was appointed to help facilitate exportation of select falcons to Spain. From paintings of neotropical raptors in Europe during this period, we know that species that would have been previously unfamiliar to Europeans, such as the ornate hawk-eagle, arrived. One of the most mysterious of the species is the Aleto, whose identity has been debated among several authors, though the aplomado falcon seems the most likely.[44] In 1616, Ferreira wrote of Nebris imported from the Castillian Indes, Alettes from the Spanish Indies and Brazil, and describes a bird that sounds similar to an ornate hawk-eagle.[97] In general reference to falconry, however, he describes the "oblivion into which it has fallen" and his hope that his work may revive interest. This, however, was not to be.

Although it is not known when falconry died out in the Americas, it seems likely to have paralleled the precipitous decline of the sport in Europe. In Spain and Portugal, falconry was rarely practiced after the mid-17th century.[98] Falconry does not appear to have resurfaced in Central or South America until the 20th century. In Mexico, there was a "Mexican Association of Falconry" in 1950, which like early attempts at forming formal falconry organizations in the United States, was short-lived.[59]

FALCONRY IN CENTRAL AND SOUTH AMERICA—THE PRESENT

Today there are falconers in many Central and South American countries, with multiple active falconry clubs. There is a tremendous diversity of species available for falconry in these countries, with some neotropical species being among the most attractive. The ornate hawk-eagle, Chilean hawk *(Accipiter chilensis)*, black-and-white hawk-eagle *(Spizaetus melanoleucus)*, bicolored hawk *(Accipiter bicolor)*, collared forest falcon *(Micrastur semitorquatus)*, bat falcon, orange-breasted falcon *(Falco deiroleucus)*, and other species have been trained. Familiar species often flown in other countries include peregrine falcons, aplomado falcons, and Harris's hawks.

Falconers in these countries are frequently involved in abatement or captive breeding. Veterinarians are often involved in the care of captive birds within breeding collections. Information gathered from captive breeding or rehabilitation efforts may be important in organizing conservation efforts, especially for species declining in the wild.

FALCONRY IN CENTRAL AND SOUTH AMERICA—THE FUTURE

Similar to falconry in Mexico, falconers in Central and South America face challenges that may affect the future of the sport in these regions. Agencies that would develop and oversee regulations for falconry seem to lack interest and find it easier to prohibit the capture of wildlife than to develop formal regulations (Raul Ducoing, personal communication, 2020). Even with a number of falconers acting as consultants for their respective governments, the lack of impetus for authorities to create, vote for, and implement regulations is likely due to the low number of individuals participating in falconry (Raul Ducoing, personal communication, 2020). This is the situation in Panama, Ecuador, and Peru. However, Argentina has falconry regulations, but they are scant (Raul Ducoing, personal communication, 2020).

CHAPTER 56

Toucans and Hornbills

Kathryn C. Gamble • Janis A. Raines • Peter Sandmeier • Shangzhe Xie

Visit **eBooks.Health.Elsevier.com** for a complete set of references.

While not taxonomically related, the toucan (order Piciformes) and hornbill (order Bucerotiformes) have large beaks and skull structures that provide consistent challenges to the veterinarian. Similar concerns exist in their nutritional management with regard to iron storage disease (ISD).

TOUCANS

Janis A. Raines

TAXONOMY AND ZOOGEOGRAPHY

Toucans are classified in the order Piciformes, which is comprised of four families: Indicatoridae (honeyguides), Capitonidae (barbets), Picidae (woodpeckers), and Ramphastidae (toucans, toucanets, and aracaris). The four families share similar characteristics: zygodactyly, cavity nesting, and the adults lacking down feathers.[1–3] Ramphastidae are distinguished by their colorful beaks that are overproportioned to body size. However, the internal bill structure consists of a network of bony septa that give strength while reducing its mass.[4,5] The family Ramphastidae includes 6 genera, 34 species, and 78 taxa, with the largest genus *Pteroglossus* ("feathered tongued") containing 14 species. Ramphastids are neotropical and therefore found only in Central and South America. They inhabit varied habitats within their range, from lowland rainforests to high-altitude cloud forests. While most stay below 100 to 1200 m in altitude, some species may be found at elevations up to 2700 m. The populations are stable within the home range, with only a single species considered endangered (yellow-browed toucanet, *Aulacorhynchus huallagae*).[1,2]

ANATOMY

Serrated bill tomia is a characteristic of all toucans; however, these develop slowly and may not be noted in juveniles. A structural component found only in Ramphastidae is a modification of the nine caudal vertebrae such that their extreme range of motion allows toucans to place their tail over the head. This position, assumed by toucan species while sleeping, involves laying the beak up over the back, tucking it under the scapular feathers, and then tipping up the tail to form a "feather ball".[2] This positioning is presumed to be an adaptation for cavity dwelling, but they also are noted to assume this position on open perches. Sexual dimorphism is uncommon, with sexually dimorphic plumage seen in only two genera (*Selenidera* and *Pteroglossus*).[2] Bill length and overall body size are typically larger in sexually mature male toucans than in females, but results can be inconsistent, so DNA sexing or endoscopy is more reliable. The tongue reaches lengths up to 15 cm and is laminated along the sides, with the laminae becoming more brush-like along the tip.[2] The iris of several pale-eyed species has dark areas rostral and caudal to the dark pupil giving the appearance of a slit pupil, commonly referred to as the glitch. At least three species of toucans have a postorbital ligament, which has unknown significance. The trachea normally deviates ventrally at the thoracic inlet, which is seen radiographically (Figure 56.1).[3,6] Toucans lack an ingluvium (crop), possess a poorly muscularized ventriculus, and have no ceca. The spleen is long and slender, and this family has a gallbladder.[7,8] Toucans are not strong fliers and tend to lose altitude as they fly long distances, which is why their flight is undulating with a series of flaps alternating with glides. They make a characteristic noise while flying due to narrowed (emarginate) primary feathers along the distal edge of the wings.[1]

BEHAVIOR AND REPRODUCTION

Toucan species live in large flocks or minimally have overlapping territories. However, during the breeding season, the pairs will separate into a defended territory that can cover up to 30 hectares. Breeding cycles for toucan species in the wild correspond with the rainy seasons, so breeding behaviors may be stimulated in human care by simply providing regular heavy showers daily while simultaneously increasing food abundance. Typical breeding age (2.5–3.5 years of age) corresponds with acquisition of full adult size and plumage.

Time should be taken to pair toucans compatibly. It is recommended to house birds adjacent to one another with visual contact for some time to encourage proper bonding behavior. The time interval needed to ensure good pair bonding is very individualized and hinges on the interpersonal interactions of the birds. Regular observations can help determine the timing. After this interval, the pair can be introduced into a very large aviary with minimum dimensions of 4.6 m^2 (50 ft^2) for smaller

FIGURE 56.1 Radiograph of keel-billed toucan *(Ramphastos sulfuratus)* demonstrating normal tracheal deviation at the level of the thoracic inlet *(arrow)*.

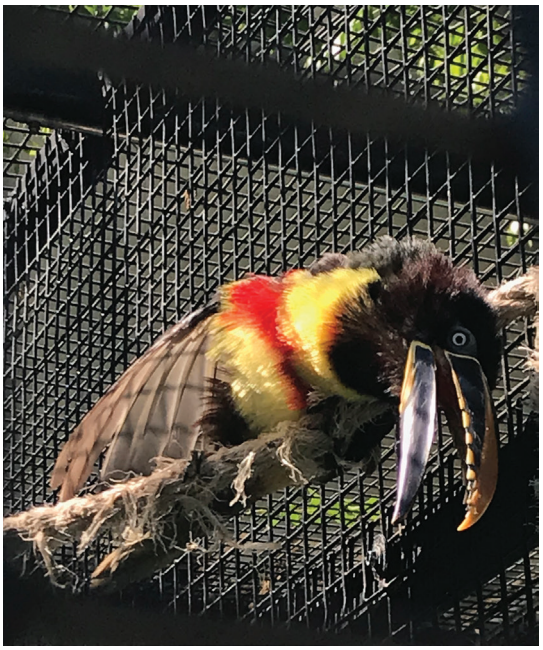

FIGURE 56.2 A chestnut-eared aracari *(Pteroglossus castanotis)* sunbathing.

species and 9.3 m^2 (100 ft^2) for larger aracaris and toucans. The aviary should contain live shrubs or structures to allow hiding locations in the advent of aggression. The aviary design should also maximize the long dimension to provide adequate flight distance. Promising signs of a successful pairing include allopreening, sitting together on a perch, feeding one another, or gentle bill tapping. Signs of aggression and incompatibility include chasing and extreme bill sparring. It is not uncommon to have fatal aggression between an established pair. Similarly, intense aggression may occur toward other pairs, requiring visual barriers between aviaries.[9]

Toucans are cavity nesters but rarely do their own excavation. Instead, they commonly use abandoned woodpecker cavities or rotted ends of branches and tree trunks. An integral part of pair bonding is the preparation of the cavity for nesting. In the wild, a breeding pair may use the same cavity for multiple years. Aviculturists can offer hollowed out palm logs to encourage breeding behavior. By filling the empty cavity of the log with wood shavings or moss, excavation behaviors can be stimulated. More basic nest boxes made of plywood can also be used, provided that nestbox dimensions are appropriate. Common dimensions for nest boxes recommended for larger toucan species measure from 70 to 100 cm in length and 20 to 30 cm in diameter, with an 8- to 10-cm-wide entrance hole. For aracaris and toucanets, the measurements are 70 to 100 cm long, 12 to 15 cm in diameter, and a 6- to 7-cm-wide entrance hole.[3] The primary difference between these is the interior dimension as this has to allow for accommodation of the longer bill length in the larger toucan species.

Ramphastids lay two to four small white eggs. Toucans can be good parents, but it is very common to pull the eggs for artificial incubation to ensure more consistent incubation parameters in captive breeding settings. This must be considered when constructing nest boxes for these species. The depth must be such that eggs (or young) can easily be reached, or an access door must be provided. If eggs are to be artificially incubated, typical parameters are 36.9 to 37.2°C (98.4–99°F) with relative humidity maintained at 65%. Incubation has an average length of 16 days. Typically, *Ramphastos* species have a slightly longer incubation (~18 days). The young are altricial and are born with tubercled heel pads, known as a tarsal-metatarsal callus. These heel pads disappear at the same time as the opening of the eyelids, at approximately 3 weeks of age. Along with a rather pendulous abdomen, this feature is thought to function as a stabilizing mechanism to keep the chicks tilted upward for easier parental feeding in the nest log. Further adaptations for a cavity lifestyle are a prognathic mandible, which begins to recede around 14 days of age, and an up-tilted uropygium. The chicks are fed throughout the day because of lack of an ingluvium. A similar schedule should be followed when chicks are being hand-reared. Feedings of small pieces of food multiple times throughout the day is most successful. Chicks typically fledge after no less than 40 days (see also Chapter 44).[9,10]

Toucans will often sunbathe after a bath by spreading feathers and draping these over a branch, which can be misconstrued as a sign of illness (Figure 56.2). Toucans also pant with an open bill to allow for cooling through evaporative action, which should not be mistaken as a sign of hyperthermia. It does bear noting that—regardless of their tropical distribution—these species can be sensitive to extreme heat, yet surprisingly tolerant of exposure to extreme cold (−6°C/20°F) as long as they are provided shelter, an adequate heat source (can be achieved using a 250 W heat bulb), and have been acclimated properly to cooler temperatures.[1,2,7]

Toucans are also mischievous both in the wild and in managed care. Their curiosity makes them both a welcome and unwelcome addition to a mixed species aviary as they have been known to destroy plantings and nests of other species. They will pick up and consume inedible objects found in their enclosures. However, as they do have the ability to regurgitate these items, foreign body impaction or gastrointestinal obstruction is not a common occurrence.[11,12]

NUTRITION

Within the varied habitats that these birds inhabit, an almost infinite variety of fruiting plants are available for feeding. While these species are primarily frugivores, it is important to remember that toucans are opportunistic omnivores. They have been known to rob nests and feed on small vertebrates, and nestlings and eggs of other toucan species as well as other avian species. The offering of insects during the nesting season can reinforce proper neonatal care. Toucans have an unusual feeding style that involves tossing a food item up in the air, catching it in an open beak, and swallowing it. Toucans are particularly prone to hemochromatosis (iron storage disease, ISD), and iron in their diet should be limited (see section on Iron Storage Disease). A variety of fruits have successfully been fed to toucans with the hypothesis that reducing citrus and high-iron–containing fruits in the diet may prevent hemochromatosis. Some aviculturists have used dietary tannin to bind dietary iron and decrease its absorption.[13] This approach has not been proven to be effective; however, it has not been found to have a detrimental effect on gastrointestinal health. In managed care, it is common practice to supplement diets with paprika or canthaxanthin to maintain bright coloration of the beak and periorbital skin. Toucans must be provided with large water-filled containers to allow both the necessary room to dip the water up with the beak as well as bathing.

MANAGED CARE AND VETERINARY CONSIDERATIONS

As detailed previously, toucans are not strong fliers, but they are very strong bounders, often moving about the aviary through leaps and hops. They are able to cause significant damage to their bill by colliding with caging walls and furniture, especially during displays or while preparing the nest log. This issue can be particularly problematic in young birds with rapidly developing beaks. Depending on the severity of bill damage, repair can be attempted using dental epoxies and, more recently, three-dimensional (3D) printing (see Chapter 31 and the section on The Hornbill Casque in Health and Disease).

Preventative medicine protocols such as those applied to other avian species can be successfully applied to ramphastids. Health screenings via blood analysis and radiographs can be useful to monitor current health status. These can be performed opportunistically, but regular fecal analysis is key to monitor parasite load. Much like hornbills, inhalant anesthesia is delivered via modified facemasks made from bags or plastic bottles (Figures 56.3 and 56.4). All other veterinary procedures can be performed similarly to other avian species, with the preferred venipuncture site being the right jugular vein.[3,14] The one caveat to this is the surgical approach to visualize the gonads, which is slightly more dorsal than that used in psittacines so as to avoid the more distended intestinal loops.[7,8]

The most common infectious diseases reported in toucans are ulcerative enteritis (*Clostridium* spp.), mycobacteriosis, herpesviral hepatitis, yersiniosis, candidiasis, aspergillosis, and capillariosis (Table 56.1).[15–17] Of these, *Capillaria* infection is probably the most common cause of mortality in toucans in managed care. Commonly, clinical signs of *Capillaria* infections include lethargy, weight loss, hypoproteinemia, and anemia. The most successful therapeutic regimen involves

FIGURE 56.3 Keel-billed toucan *(Ramphastos sulfuratus)* in modified 1-L fluid bag as facemask for anesthetic induction.

FIGURE 56.4 Modified fluid bags for use as anesthetic facemask *(above)*, and fluid container with bandaging material to contain anesthetic gas being delivered *(below)*.

removing exposure to reinfection, which may only be accomplished by hospitalization on a concrete floor, and an intensive parasite control (fenbendazole 50–100 mg/kg PO for 5–7 days, alternating with or in conjunction with ivermectin 0.2 mg/kg PO/SC/IM for 3–4 treatments given 1 week apart).[3,7,8,14]

Historically, of noninfectious diseases, diabetes mellitus was commonly reported in toucan species, but reports have decreased in more recent years.[18] It is unknown if improvements in diet and management are contributing factors to this change in incidence.

HORNBILLS

Kathryn C. Gamble

TAXONOMY AND ZOOGEOGRAPHY

Hornbills were previously included in the order Coraciiformes, but due to their limited anatomic and behavioral similarities with other birds in that group, they were reassigned to the order Bucerotiformes.[19] Together with the clade of ground hoopoes and wood hoopoes, to which hornbills have been linked ancestrally, they are included in the overarching superorder Bucerotes.[19] By their colorful oversized

beaks, these strictly Old World species bear some phenotypic resemblance to the New World toucans of the order Piciformes; however, it continues no further than this feature as described elsewhere in this chapter (see section on Toucans).[19] The elaborate casques define this order and vary by each of the individual species as detailed in the section on The Hornbill Casque in Health and Disease.[19,20]

The order contains two families: Bucorvidae and Bucerotidae. The former is limited to ground hornbills within the genus *Bucorvus*. These two African *Bucorvus* species are considered the ancestral hornbill.[19] The remaining 55 species are distributed nearly evenly between 4 African and 10 Asian genera as distinguished by body size, habitat, chick-feeding strategies, and characteristic color patterns and calls (Table 56.2).[19,20] *Tockus* are considered the earliest taxonomic diversion of the African species, and *Anorrhinus* the comparable separation for the Asian species.[19,20] While African species are divided evenly between habitats of woodland and savannah or evergreen forest, only one Asian species lives in any habitat other than evergreen forest, and most Asian species are island inhabitants.[20] Interestingly, although no extant genera are found in both Asia and Africa, taxonomic bonds between the African *Bucorvus* and the Asian *Buceros* have been identified by a shared genus of *Bucerophagus (Mallophaga)* chewing lice, which suggest an earlier radiation.[19–21]

ANATOMY

Shared anatomic features of the Bucerotidae include[20,22,23]: (1) united maxillopalatine bones (desmognathous arrangement); (2) primitive stapes within the middle ear; (3) syndactylism of pedal digits 2 to 4; (4) bilobed kidneys due to the absence of the median lobe characteristic of the trilobed kidney of other birds; and (5) lack of the following structures—ceca, ambiens muscle, and stylohyoideus muscle. The beak is curved and always meets at the rostral tips where it is used dexterously to manipulate food items.[19,20] However, with its absent retractor muscle, the fleshy short tongue is not useful for food manipulation, so the beak is also used to toss these items into the caudal oral cavity for ingestion.[19,20] Due to the placement of their eyes and positioning of the beak, hornbills are able to scan overhead and see to and over their bill tip with excellent binocular vision that further facilitates food manipulation.[19] Species of *Buceros* and *Tockus* have an external directional of beak growth that parallels the inner surfaces such that smooth tomia develop, although only in the *Tockus* do the tomia actually appose.[19] In the other

(Courtesy Kimberlee Wojick, Roger Williams Park Zoo.)

hornbill species, beak growth occurs such that jagged edges develop along the tomia for crushing and holding food items.[19] *Aceros* develop annular grooves at the caudal rhinothecal base that allow some staging of age until full sexual maturity is achieved.[19,20] Additional to the casque, and likely a result of it for needed structural support, the hornbill's axial skeleton presents two other unique features: (1) fusion of the atlas and axis and (2) two vertebral articulations with the caudal skull at the basio- and supraoccipital condyles (Figure 56.5).[19,20,23] Ground hornbills have 15 cervical vertebrae, which is considered primitive to the 14 cervical vertebrae of the other Bucerotidae; they also lack carotid arteries. Ground hornbills furthermore have a separate tendon that connects the pelvis to the femur allowing them to reach their pes to the head rather than indirectly over the wing, as is typical for many birds.[20]

Plumage coloration of hornbills is monochromatic in gray to black, and occasional brown, but patterns of white are striking and localized for visual signaling, especially during flight.[19,20] Their feathers are coarse and have a fluffed texture as more hair than plume, and palpebrae present marked cilia (eyelashes).[19,20] All hornbill species lack ventral covert feathers on both primary and secondary feathers, which reduces muffling during flight, such that larger-bodied species utilize this sound as part of their auditory signaling.[19,20] Much more resplendent than the plumage are the casque and beak, which are colorful in species-specific hues and patterns. Additionally, the *Buceros* and *Rhinoplax* species utilize their carotenoid-rich uropygial gland secretions as a cosmetic applied to their beak and casque until they are intensely orange, yellow, or red-orange.[19,20,23] Males of all species tend to be larger than the females in body size and wing span and, most dramatically, in bill length, with an 8% to 30% variation.[20] Aside from these morphometrics, patterns of the plumage and coloration of beak and casque and, in some *Buceros*, *Rhyticeros*, and *Ocyceros* species, the iris make all hornbill species sexually dimorphic as mature adults.[19,20] However, juvenile hornbills vary widely by species as to whether they resemble more the male or female parent until sexual maturity.

BEHAVIOR

Hornbills spend an inordinate amount of their behavioral and diurnal time budget preening their own plumage and that of social companions.[19] This care prominently features behaviors of bathing in open water or other sources of moisture in addition to feather manipulation by the beak. Sunbathing, sometimes employed as a warming mechanism, includes unusual, contorted posturing.[19,20] Generally heavy-bodied birds, hornbills tend to hop more than walk on the ground. Exceptions are the ground hornbills and clucking *Tockus* species that have proportionately elongated tarsi and tend to stride.

REPRODUCTION

Hornbills are long-lived with extended intervals for successful reproduction often predicated by available food resources.[19] It would be remiss to continue without description of the sealed cavity nesting strategy of all hornbills, except *Bucorvus*, which use open cavities without a seal.[19,20] This behavior has an extensive impact on the taxonomic features of anatomy, physiology, and behavior. Hornbills are seasonal breeders. African savannah and woodland species nest before the rains commence, and ground hornbills nest in later months once vegetation has grown. Asian species nest at the onset of the cool dry season. In the United States, *Buceros* breeding was documented in January through April.[24]

Extended courtship and conspecific feeding occur between adult pairs that culminate in confirmation of an identified natural cavity as the nesting site suitable to the female.[19,20,24] Repeated copulations occur during the latter stages of this period, and extended fertility of spermatozoa within the female reproductive tract of up to 3 weeks has been established.[19,20,22] Ultimately, the bred female enters the cavity and using the trowel-shaped beak, generally will complete all the entry sealing to a narrow vertical slit.[19,20,24] Material used for the seal includes soil, feces, and soft foods.[19,20,24] Specifically in *Bycanistes* and *Ceratogymna*, the male produces mud pellets from ingested dirt that are carried to the nest for the female to use. Male *Tockus* and *Anthracoceros* provide mud directly to their mate, with this material essentially being the sole product used for the seal by the latter genus.[19]

The female commences oviposition of oval eggs with pitted shells, and asynchronous incubation begins immediately due to the confines of the nest.[19,20,23] Smaller species lay up to eight eggs at daily intervals, while larger species lay fewer eggs at a longer interval of up to 5 days. Eggs are incubated for 23 to 42 days, with smaller species being at the lower and larger species at the higher end of this range.[19] Females of *Tockus*, *Buceros*, and *Bucorvus* depart the nest at the midnesting interval, then the chicks reseal the chamber opening using food and feces so that they can resume their protected growth period.[19] Similar to the female's entry, females and chicks depart in an orderly fashion from the chamber with first the head and neck, then one wing ahead of the torso, followed by the second wing, and the legs.

In the female, concurrent with the incubation of the eggs, an entire molt is initiated starting with all rectrices (10) and rapidly progressing to the remiges (10 primaries and 12 secondaries), such that for most of the incubation and nesting period, she remains flightless.[19,20] Dependent on the species, the molt is completed either at midpoint of chick rearing or at chick emergence from the nest. Males complete a more typical molt of only a few feathers at a time and on opposite sides of the body, and generally following complete emergence of the family.[19,20]

While it has often been considered from the vantage of high dependence of the female on the male in this arrangement, it must be considered that the male is equally reliant on its mate's success within the cavity to assure its contribution to the next generation. Due to the extensive work imposed by this unique nesting activity, roughly 30% of the hornbill species employ cooperative feeding and nest assistance by immature or unpaired, but related, males.[19,20]

NUTRITION AND FEEDING

Feeding strategies of the hornbills range from highly carnivorous to essentially frugivorous. Fruits are selected for their moisture content and lipid and carbohydrate components and include syconia and drupes.[19,20] Hornbills, as a rule, do not drink water but obtain water from their foods.[1] As these birds act as seed dispersers, the selected fruits separate easily from their seeds following ingestion and then either are disgorged or defecated intact.[19] All hornbills, even strict frugivores, increase their protein intake during the breeding and nesting season due to the high demands of the females' incarcerated molt and growing chicks. This diet change generally is accomplished by whole prey consumption and increased omnivory.[19,20,23] Figs (*Ficus* spp.) are emphasized in the diet when they are in season as they contain a high content of protein at 6% to 12% by weight and increased calcium.[19]

Characteristic food carriage to the female adult and nestlings is used as differentiation for genus and species[19,20]: *Bucorvus* carry multiple prey items bundled along the beak; *Tockus* carry single prey items, usually insects, at the beak tip; *Ocyceros* and most other species swallow multiple fruit items into the cranial gastrointestinal tract to be disgorged singly at the nest, although the larger hornbills that have a higher degree of omnivory will also carry individual prey items in the beak to the nest. As chicks hatch asynchronously in order of their laying, in times of reduced food resources, younger chicks may perish and serve as food for their larger, older siblings.[19,20,22]

Carnivorous hornbills are thinly spread in their habitats and considered territorial.[19,20] Some carnivorous hornbill species have developed compatible relationships with other animals in their habitats to improve success of finding prey.[19] By contrast, communal interactions are encouraged by the frugivorous feeding strategy, with sharing of food sources and less territoriality being demonstrated, except at nesting sites, which are a limited commodity.[19,20]

Regardless of the natural history, housing in managed care generally occurs in bonded pairs, or as family groups with recently emerged chicks (Figure 56.6). In managed care of *Buceros*, increased behaviors related to pair bonding, nesting, and mudding the seal were noted in successful chick production years, and a potential for increased compatibility to develop seemed evident with increased duration of the pairing.[24]

NEONATOLOGY

Following hatching, nesting periods for smaller species of hornbills are 39 to 50 days and for larger species 72 to 96 days.[19] Chicks hatch with a marked prognathism that resolves with beak elongation within the first days of life. Chick beaks also lack the species-characteristic casque, aside from a thickening in the area where future maturation will occur.[19,20] These altricial chicks maintain their eyes closed for 10 days. They are also bare of feathers for this period until suddenly they are covered in unsheathed quills over a rapid period of days (Figure 56.7), which can be concurrent with skin darkening.[19,20,23] This "porcupine stage" is replaced equally abruptly by a nearly fully feathered state as the quill sheaths are shed and the plumage unfurls in the drab color phase at one-third of the nesting interval.[19] In the first weeks of the nesting period, pockets of subcutaneous emphysema develop at the shoulders, then move and accumulate gradually across the entire torso, legs, and wings of the chick, which is maintained into adulthood as a normal finding. These chicks spend much time resting on their plantar hocks on roughened nest

substrates while confined within the small nest cavity. Prominent plantar tarsal skin callosities are present and considered to provide padding in this situation. At the end of the first third of the nesting stage, the chicks' legs will have attained the adult length for the species, which allows them to stand successfully and unassisted at the nest cavity vent to accept feeding and expel feces from the chamber interior. Flight and tail feathers are completely grown at the time of chamber emergence.[19]

MANAGED CARE AND VETERINARY CONSIDERATIONS

Confident handling of hornbills requires secure restraint of the head and casque due to their heavy nature and strength.[5] As the casque is large and the external nares are at the beak-casque interface, standard anesthetic masks should be replaced by clear plastic bags or sheaths to allow visual access to the patient but create a soft chamber around the ornamental keratin (see section on Toucans; Figures 56.3 and 56.4).[23] Peripheral venipuncture and radiographic interpretation (Figure 56.8) are impacted by the previously described subcutaneous emphysema. However, subcutaneous fluids can be administered without concern of respiratory impact or entry to the internal air sacs.

Considerations of geriatric age and events in managed care should be managed for this species as they are exceptionally long-lived, with the larger species reaching 40 to 50 years old and even smaller species routinely aged over a decade. Additionally, their high level of curiosity lends these birds to concern for foreign body ingestion. That said, no truly unique diseases to the order can be remarked aside from the species-focused squamous cell carcinoma of the giant hornbill *(Buceros bicornis)* casque, which should be monitored routinely by annual skull radiography (see section on The Hornbill Casque in Health and Disease). With a shared etiologic concern of dietary carotenoids, great vessel atherosclerosis also is featured frequently in later decades of life for giant hornbills. Due to the predominantly frugivorous nature of Asian hornbills, hemochromatosis or ISD has figured prominently in their managed care (see section on Iron Storage Disease). Otherwise, intermittent cases of bacterial, fungal, parasitic, toxicologic, or orthopedic conditions were not found at extraordinary or frequent levels aside from proventricular spiurid infections in juvenile wrinkled hornbills *(Rhabdotorrhinus (Aceros) corrugatus)*.[23]

IRON STORAGE DISEASE

Peter Sandmeier

Although Iron Storage disease (ISD) has been described in many avian species, both hornbills and especially toucans are commonly affected, leading to discussion of the disease within this chapter.

REGULATION OF IRON HOMEOSTASIS

Iron is an essential trace element but also is toxic in excess. All iron enters the body from the diet, either as heme or nonheme iron. Most heme iron is animal derived as myoglobin or hemoglobin. In contrast, nonheme iron is plant derived. As heme iron is bound within a protoporphyrin ring, its absorption is more efficient and is less affected by diet composition than nonheme iron bioavailability, which can be affected by a range of dietary constituents. The low pH of the stomach and other organic acids, such as ascorbic acid, maintains nonheme iron in its ferrous (Fe^{2+}) form, which is the soluble, more absorbable iron form. In contrast, ingested plant-derived phytates and polyphenols can bind nonheme iron and impede its absorption.

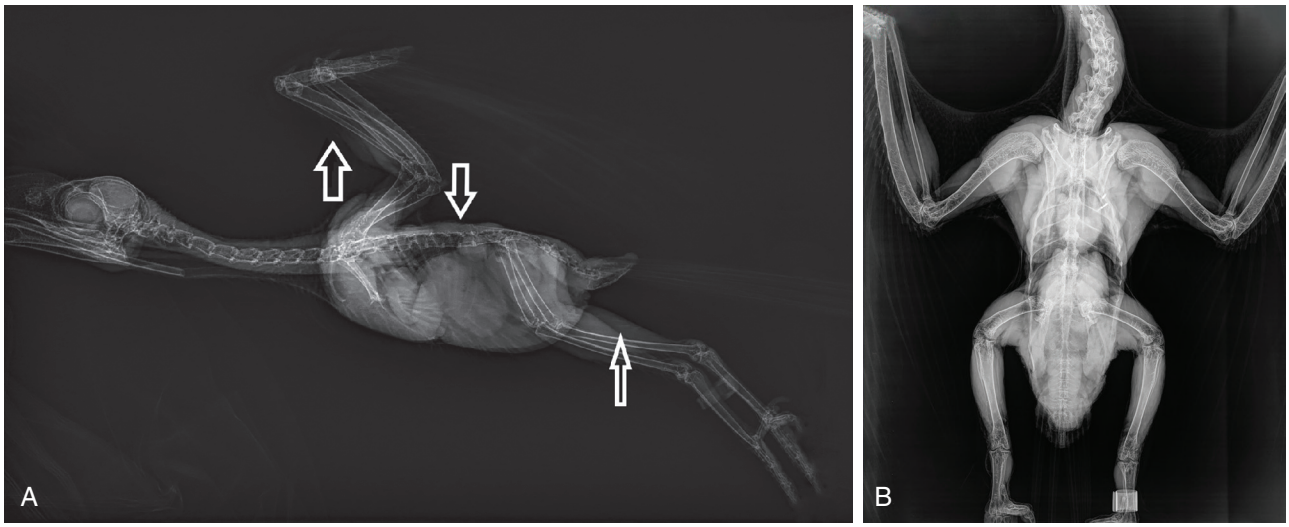

FIGURE 56.8 Subcutaneous emphysema normally present in all hornbill species to a variable degree, beginning as nestlings and maintained as adults, as shown in (A) the lateral radiograph of an adult male Von der Decken's *(Tockus deckeni)* as noted by *arrows* and (B) the ventrodorsal radiograph of an adult female Blyth's *(Rhyticeros plicatus)* hornbill. (Radiograph provided by Nancy Carpenter, Utah's Hogle Zoo, and by author, respectively.)

Iron is absorbed by enterocytes mainly in the small intestine. Nonheme iron crosses the enterocyte membrane via divalent metal-iron transporter 1 (DMT1). This transporter requires ferrous iron (Fe^{2+}) as a substrate, whereas ferric iron (Fe^{3+}) is poorly absorbed by enterocytes and needs to be reduced to ferrous iron before it can bind to DMT1 and be absorbed. If iron is not immediately required by the body, it becomes sequestered in the enterocyte cells within the iron storage protein ferritin and is lost from the body once that enterocyte is sloughed. When iron is required, it is transported across the inner enterocyte wall into the bloodstream via ferroportin 1 (FPN1).

Within the bloodstream, absorbed iron is bound to plasma transferrin. Each transferrin molecule can bind two iron atoms, becoming diferric transferrin. Normally, only approximately 30% of the iron-binding sites on the plasma transferrin are occupied, providing a considerable buffering capacity. However, in ISD, transferrin becomes saturated and the concentration of toxic nontransferrin-bound iron (NTBI) can become dangerously high.

Diferric transferrin delivers iron to cells by binding to transferrin receptor 1 (TFR1) in cell membranes. Iron that is released from transferrin moves into the cytoplasm via DMT1. Iron as NTBI also can very efficiently cross the membranes of many cell types. Once inside a cell, iron is either utilized for metabolic functions or bound to the iron-storage protein ferritin for later use. As a safety valve, cells can export iron via FPN1.

Ferritin is the major intracellular iron-storage protein. Ferritin has a large iron-binding capacity and is expressed in high quantities when intracellular iron concentrations rise, providing cells with an enormous ability to sequester iron. As the concentration of iron-laden ferritin rises within the cells, these ferritin molecules aggregate and fuse to lysosomes, resulting in Fe^{3+} cores and peptides. This hemosiderin is particularly prominent in the cells of patients with ISD. The fact that small amounts of ferritin are secreted from the cell and that the secreted amount correlates with the concentration of intracellular iron makes serum ferritin concentration a useful indicator of body iron stores used in human medicine.[25]

The regulation of iron homeostasis at the cellular level is replicated at the whole-body level. This regulation is mediated by hepcidin, a small liver-derived peptide. During iron overload, the liver increases the expression of hepcidin. Hepcidin binds to the cellular iron-exporting protein FPN1, impeding the release of iron into the circulation. In contrast, when iron demands are high, hepcidin concentrations are low, the cellular iron-exporting protein FPN1 remains free, and more iron can enter the circulation. The main iron-exporting cells include macrophages, which recycle heme-derived iron from red blood cells; hepatocytes, which are the major site of iron storage; and enterocytes, where dietary intake of iron is facilitated (Figure 56.9).[25]

Two hepcidin-like cDNAs (HP1 and HP2) have been isolated from and described in pigeons. The expression of pigeon

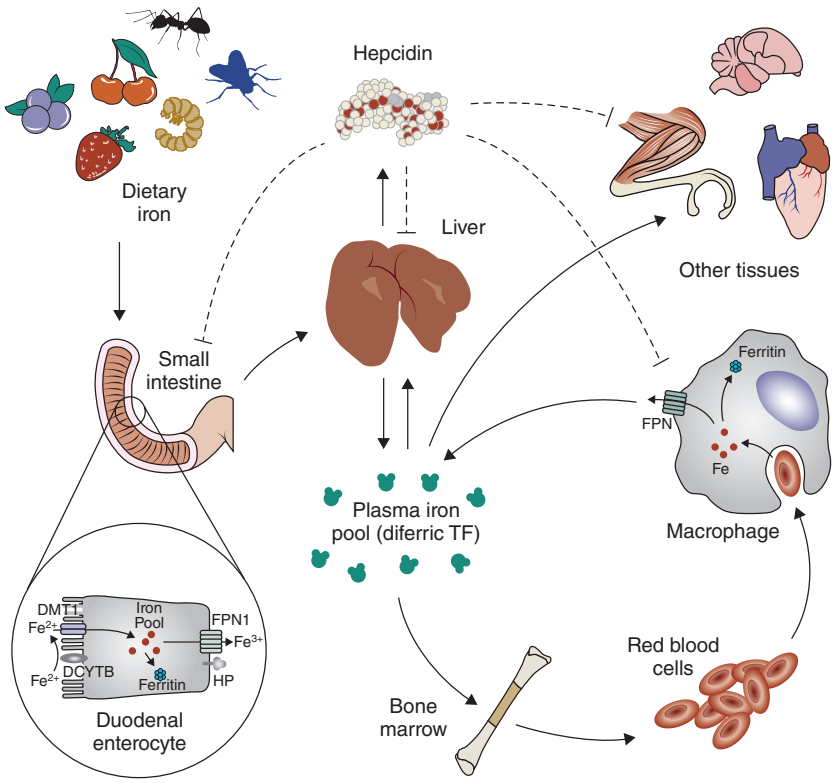

FIGURE 56.9 Body iron homeostasis. Nonheme iron enters the circulation after traversing the enterocyte. Iron binds to plasma transferrin and is distributed to tissues throughout the body. Quantitatively, most iron is used by immature red blood cells in the bone marrow for hemoglobin production. Liver-derived hepcidin binds to plasma membrane FPN1 on enterocytes, macrophages, and most body cells reducing iron absorption and impairing iron release from stores. *TF,* Transferrin.

HP1 was significantly upregulated after an iron-dextran injection, whereas the expression of HP2 did not increase, although it significantly increased after a lipopolysaccharide (LPS) injection. Therefore whereas HP1 appears to be involved in iron regulation, HP2 appears to be part of the acute phase reaction of an inflammatory response.[26]

IRON STORAGE DISEASE IN HUMANS AND OTHER MAMMALS

In humans, primary iron overload has a genetic basis resulting from mutations in genes that are involved in the transport or regulation of iron and is considered uncommon to rare. However, hemochromatosis is relatively common in white northern European males and is featured by the lack of hepcidin expression, which results in the inability to limit the absorption of dietary iron. Secondary iron overload is associated with blood transfusions that are used to treat inherited disorders such as iron-loading anemias.[27]

In other mammals with susceptibility to ISD, particularly frugivores and browsers, a similar pattern to avian species can be observed. Rather than a genetic background, a dietary component is related to the development of disease.[28]

IRON STORAGE DISEASE IN SUSCEPTIBLE AVIAN SPECIES

ISD has been described with a low incidence for many avian species in managed care. A retrospective study representing 52 genera from 13 orders reported some degree of iron accumulation in the liver of 64% of all samples, with no statistical difference in the occurrence of iron accumulation between families, orders, or origin (free ranging or managed). However, only two of the studied cases showed severe iron accumulation and clinical signs compatible with ISD.[29] Particularly susceptible or typically described species include those in the families Paradisaeidae (birds-of-paradise), Ramphastidae (toucans), Sturnidae (mynahs and starlings), Thraupidae (tanagers), Bucerotidae (hornbills), Pipridae (manakins), and Trogonidae (trogans, quetzals).[30–32] Evaluation of a large number of histopathologies in hornbills concluded that, although not as prevalent as in mynahs and toucans, frugivorous Asian hornbills, especially the genera *Aceros*, *Rhabdotorrhinus*, and *Rhyticeros* should be considered susceptible to ISD, but not necessarily the carnivorous and omnivorous species.[33]

A common characteristic of these species above is their frugivorous and, to a lesser extent, insectivorous diet. On the other hand, granivorous and omnivorous species are less likely to develop ISD.[32] Based on this observation, a common evolutionary background driven by the low iron content of their natural diet would explain the susceptibility of the affected species. However, although a low iron content of these diets can be assumed, it has only been demonstrated quantitively for free-ranging toucans.[34] Such avian species may have developed physiologic mechanisms to extract dietary iron very efficiently.[35] Higher rates of mucosal transport of iron in frugivorous mynahs than in granivorous pigeons have been demonstrated,[36] which are linked to a very high intestinal expression of iron transporters.[37]

The hypothesis that diet plays an essential role in the susceptibility of species to ISD is also supported by the fact that granivorous psittacine birds are not especially susceptible to ISD, in contrast to lories that eat predominantly nectar, fruit, and insects,[38] and red-spectacled amazons *(Amazona pretrei)* that consume a diet of mostly pine nuts containing a very low concentration of iron.[39] Similarly, among Columbidae, only frugivorous species appear to be susceptible to ISD, with the granivorous species being less commonly affected.[36]

In summary, avian species with high susceptibility to ISD that seemingly have evolved to consume diets with a low iron content appear also to have developed a very efficient iron absorption with concurrent reduced ability to downregulate iron absorption outside of their normal habitat. It seems plausible that they are not able to express hepcidin or that hepcidin does not bind to their FPH1 receptors. In managed care, these birds may develop ISD when they are fed diets containing iron concentrations that exceed their physiologic iron homeostatic capabilities[32] or containing fewer dietary components that can bind iron in the diet and impede its absorption, such as plant-derived phytates and polyphenols.

IRON STORAGE DISEASE AND INFLAMMATION

Because iron is the first limiting nutrient for the growth of many microbes in extracellular and intracellular fluids, a change in iron metabolism could offer protection against many pathogens.[32] Many ISD cases in nonsusceptible avian species occur concurrently with inflammatory diseases. A retrospective study of 180 birds representing 40 mainly nonsusceptible species showed a higher incidence of iron storage in Kupffer cells in birds that died from concurrent infectious disease than those that died from other causes.[40] In greater *(Phoenicopterus roseus)* and lesser *(P. minor)* flamingos with pododermatitis and renal amyloidosis, numerous individuals were diagnosed with ISD, suggesting that the increased iron storage is contributory to the overall inflammatory state (S. Xie, personal communication, 2020).

In mammals, the acute phase inflammatory response results in decreased absorption of iron and diversion of iron from erythropoiesis to storage sites, leading to functional iron deficiency, increased liver iron content, and subsequently to anemia. Once the inflammation is resolved, erythropoiesis resumes, stopping the anemia and reducing the liver iron.[32]

In contrast to mammals, anemia is not a hallmark of infection in avian species and plasma iron concentrations only decrease slightly during acute phase response even though liver storage increases.[32] Thus iron metabolism in avian species differs in that, during the acute phase response, diversion of extracellular iron to the liver is not accompanied by decreased absorption of iron and decreased hematopoiesis. This subsequently leads to an increased flux of iron that is deposited firstly in Kupffer cells and other phagocytes and then in hepatocytes.[32]

PATHOPHYSIOLOGY OF IRON STORAGE DISEASE

Although the mechanisms of cellular damage in avian species are not known, they are likely to be similar to those described in laboratory rodents. Iron accumulation within the lysozymes and mitochondria causes rupture and release of ionic iron, leading to oxidative damage to membranes and proteins.

Apoptosis or, in more severe cases, necrosis results. Reparative responses will cause fibrosis.[32]

DIAGNOSIS OF IRON STORAGE DISEASE IN AVIAN SPECIES

Clinical Signs

Early clinical signs of ISD are nonspecific; ISD should therefore be suspected in any diseased bird of a known susceptible species. During early stages of the disease, most patients will only show general listlessness and loss of feather glossiness.[41] Many birds will also die unexpectedly without previously noted clinical signs.[42]

As the disease progresses, clinical signs of liver disease develop, including dyspnea (due to abdominal distention as a sequela of ascites or hepatomegaly), weight loss, or depression. On thorough palpation of the coelom, ascites typically will be readily apparent, and hepatomegaly can be suspected by a flat or convex rather than concave ventral abdominal wall.[35,41]

Radiology

The most likely radiographic changes seen in birds with ISD include hepatomegaly or ascites. However, a lack of hepatomegaly does not exclude ISD. Other possible radiographic signs can include splenomegaly or cardiomegaly due to pericardial effusion.

Clinical Chemistry and Hematology

Changes in hematology or clinical pathology cannot definitively diagnose ISD. However, abnormal values that are indicative of liver damage in susceptible species make a tentative diagnosis of ISD more likely. Such changes may include increases in lactate dehydrogenase (LDH), aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma glutamyltranspeptidase (GGT), alkaline phosphatase (AP), and bile acids, although these vary by species.[43] Elevated AST, creatine phosphokinase (CK), and severe hypoproteinemia were observed in three Grey parrots *(Psittacus erithacus)* exposed to a carnivorous diet and diagnosed with ISD.[44]

Serum Iron Assays

In humans with suspected ISD, it is recommended to measure serum concentrations of ferritin and total serum iron, as well as total iron-binding capacity. Transferrin saturation is calculated by dividing the serum iron concentration by the total iron-binding capacity. However, serum ferritin concentration correlates with total body iron stores but does not correlate with the amount of iron deposited within the liver or spleen.[45]

In a case series that included 24 toucans of eight different species, iron assays of total serum iron concentration, total iron-binding capacity, and urine iron-binding capacity were all within assumed normal ranges for toucans, even though 19 of the 24 birds had liver iron concentration greater than 2000 ppm as measured by biopsy.[46] Normal amounts of hepatic iron in different managed avian species were reported to range from around 100 to 300 ppm.[46] Hence, in avian species, there seems to be no apparent correlation between serum iron assays and the amount of iron deposited in the liver.

In hornbills presented with clinical ISD, the total serum iron concentration decreased during chelation treatment, making the monitoring of total serum iron concentration a possible noninvasive method of monitoring the success of chelation therapy.[41]

Liver Pathology

Liver biopsy is the only reliable method of obtaining an antemortem definitive diagnosis of ISD. In hematoxylin and eosin–stained histological samples, iron accumulation is recognized as yellow-gold to brown granular pigment in the cytoplasm of hepatocytes.[47] In Prussian blue stains, the liver iron content stains blue in contrast to the red stain of liver parenchyma that is not loaded with iron.[41]

Histopathologically identified increased iron content in the liver without concurrent cellular damage cannot be considered a diagnosis of ISD. The changes consistent with ISD include severe iron deposits in hepatocellular and Kupffer cells, hepatic periportal macrophages, and splenic phagocytes, as well as portal bridging fibrosis, biliary hyperplasia, and mild lymphoplasmacytic, heterophilic cholangiohepatitis.[31,38] Histological evidence of ISD has also been described in other organs. Various authors describe acute myocardial necrosis,[38,44] which may in many cases be the final cause of death. Moderate to mild iron deposits also are described in the spleen, myocytes of the heart, pancreatic acinar cells, intestinal enterocytes, and renal tubuloepithelial cells.[38]

QUANTIFICATION OF LIVER IRON CONTENT

Three different methods of quantifying liver iron content have been described: chemical-toxicological analysis, quantitative image analysis (QIA), and magnetic resonance imaging (MRI).

Chemical analysis is the standard method of measuring liver iron content. Measurements are performed on a liver sample, collected by liver biopsy or on postmortem, using an atomic absorption spectrometric analysis system with a spectrometer. Results of chemical analysis are reported in mg/kg of dry matter.[41]

Quantitative image analysis is performed in formalin-fixed histologic samples embedded in paraffin and sectioned according to standard techniques. Samples are then stained with Prussian blue. The mean percentage of the blue-staining area in relation to the entire area is determined with a computer-based image analysis system. Results of QIA are reported in percent (Figures 56.10 and 56.11).[48]

Because MRI is noninvasive, it has become the method of choice in calculating liver iron content in human patients. The calculated liver iron content is reported in mg/kg tissue.[49] This method has been applied experimentally in pigeons *(Columbia livia domestica)* with induced iron overload[50] and has been used to monitor the efficacy of chelation therapy with deferiprone in two Papuan/Blyth's *(Rhyticeros plicatus)* and one long-tailed *(Tropicranus albocristatus)* hornbill with hepatic ISD (Figures 56.10 and 56.11).[41] The small size of the avian patients challenges this modality. The results obtained in the hornbills had a wide standard deviation and may be inaccurate because of severe pulsation artifacts. Although results indicated a similar reduction in liver iron content as the biopsy measurements, they did not correlate significantly with these measurements.

Further, promising as MRI measurements may be, the advantage of a noninvasive monitoring must be compared with

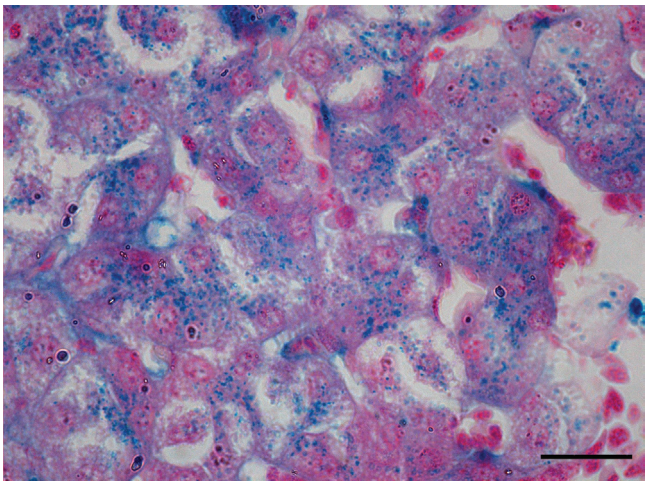

FIGURE 56.10 Prussian blue stain of a liver biopsy from a long-tailed hornbill *(Tockus albocristatus)* diagnosed with iron storage disease. Quantitative image analysis determined a hepatic iron content of 23.1%. Bar = 20 μm. Sandmeier, P., Clauss, M., Donati, O. F., Chiers, K., Kienzle, E., & Hat, J. (2012). Use of deferiprone for the treatment of hepatic iron storage disease in three hornbills. J Am Vet Med Assoc 240(1), 75–81.

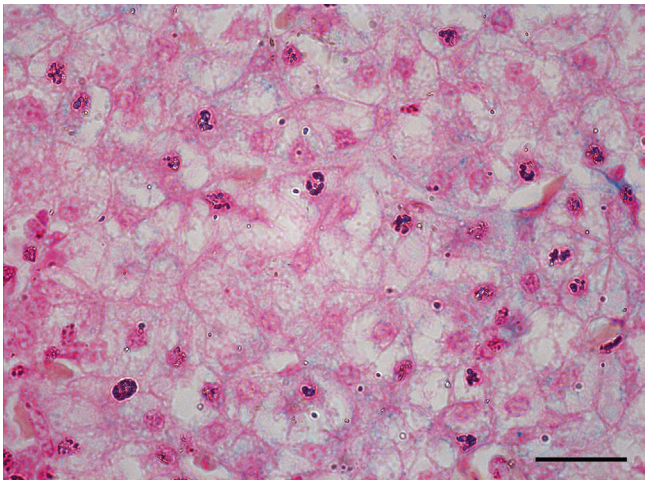

FIGURE 56.11 Prussian blue stain from the same hornbill as in Figure 56.10 after 90 days of chelation therapy with oral deferiprone. Quantitative image analysis determined a hepatic iron content of 0.7%. Bar = 20 μm. Sandmeier, P., Clauss, M., Donati, O. F., Chiers, K., Kienzle, E., & Hat, J. (2012). Use of deferiprone for the treatment of hepatic iron storage disease in three hornbills. J Am Vet Med Assoc 240(1), 75–81.

the risks of the relatively long period of general anesthesia required (60–80 minutes for MRI vs 10–15 minutes for biopsy), which is an important constraint, especially in birds of a generally reduced health status. Additional logistic challenges of longer transport routes and preparation time will increase stress for the bird related to the medical procedures. Nonetheless, with increasingly widespread availability of MRI equipment and trained personnel in veterinary referral and teaching hospitals, the use of this technology for noninvasive diagnosis of ISD in appropriately selected and monitored avian patients, particularly exotic birds of high economic value, is likely to be indicated.[41]

TREATMENT OF IRON STORAGE DISEASE

For successful treatment, it is important to be able to make a diagnosis at an early stage before the disease progresses. Three therapeutic options have been described for the treatment of ISD: phlebotomy, iron chelation therapy, and dietary modification.

Phlebotomy is the most common treatment for ISD in humans.[51] Whole blood phlebotomy performed once or twice weekly by removing a blood volume of 0.7% of the body weight is recommended. If anemia occurs, then chelation therapy with deferoxamine administered parentally or deferiprone as an oral chelator is recommended.[51] While no guideline for avian phlebotomy has been standardized, blood volumes of 0.5% to 1% of body weight have been recommended as a safe maximum.[52]

Considerations during the use of phlebotomy in avian patients would include stress, risks of repeated anesthesia, injury during capture, hematoma formation, and induction of anemia. It is prudent to closely monitor the hematocrit and hemoglobin in avian patients treated by phlebotomy.

Chelation therapy in avian patients has been described using parenteral deferoxamine (100 mg/kg q24h) as well as oral deferiprone (100 mg/kg q24h). Deferoxamine is a parental chelator that forms stable complexes with iron, preventing the iron from being involved with further reactions. It binds preferentially with ferritin and hemosiderin forms of iron but not transferrin, cytochromes, or hemoglobin. The chelated iron is metabolized by plasma membranes and is excreted in urine and feces.[53] The disadvantage of deferoxamine chelation therapy is the necessity of daily injections. Deferiprone is an orally bioavailable bidentate ligand with iron-chelating activity. Deferiprone binds to iron in a 3:1 (ligand:iron) molar ratio. As deferiprone can be administered orally, this medication represents a more viable option for long-term treatment.[41]

Dietary modification entails feeding a low-iron diet with or without adding iron-binding substances, including polyphenols such as tannins or phytates. It also should be recommended to avoid substances, such as ascorbic acid, which enhance iron absorption.[54]

In a study performed in European starlings *(Sturnus vulgaris)*, the liver iron concentration after four different treatment methods was compared among each other and to a control group of seven euthanized wild starlings.[55] After feeding a loading iron diet, all groups were fed a low-iron diet containing 25 ppm of iron. Group 1 (n = 4) was treated with the low-iron diet only. Group 2 (n = 4) was fed a phytate (inositol) and tannic acid in addition to the low-iron diet. Group 3 (n = 4) was treated with deferoxamine (100 mg/kg SC q24h) and fed the low-iron diet. Group 4 (n = 4) was treated with weekly phlebotomy and fed the low-iron diet. In groups 3 and 4, the mean liver iron concentration was significantly decreased after 16 weeks of treatment in comparison to the control group. The decrease in liver iron concentration in group 1 was small but was significant when compared to control starlings. No significant decrease in liver iron concentration occurred in group 2 when compared to the control starlings.

In a further recent study, the effect of oral deferiprone at 75 mg/kg q24h and subcutaneous deferoxamine at 100 mg/kg with or without phlebotomy was studied in healthy common mynahs *(Acridotheres tristis)* that were euthanized posttreatment and liver iron, copper, and zinc concentrations were analyzed. After 1 month, in all treatment groups, the levels of iron, copper, and zinc present in the liver were significantly reduced, but no significant difference was noted in metal concentrations between the groups significantly reduced, but no significant difference was noted in concentrations between the treatment groups. After 2 months of treatment the liver iron, copper, and zinc concentrations decreased further. However, this decrease was only significant in the group treated with deferiprone and phlebotomy. The authors concluded that all treatment options successfully reduce liver iron content within 1 month and recommend the use of deferiprone as an inexpensive oral chelator. They recommended not treating longer than 1 month, as longer-term treatment causes iron, zinc, and copper deficiency.[56]

Pharmacological studies have been performed on the oral iron chelator deferiprone in pigeons and chickens *(Gallus gallus domesticus)*. The pharmacokinetics of the two species were very similar. In pigeons and chickens, an oral administration of deferiprone at a dose of 50 mg/kg achieved plasma concentration effective for iron chelation for at least 8 hours. No significant alterations in routine hematological or biochemical parameters were noted.[53,57,58] In both species, oral chelation therapy was associated with weight loss and reduced zinc serum concentrations. In chickens, a reduction in egg production and death, most likely due to acute reduction in iron required for normal enzymatic processes, was observed.[58] Based on the half-life of deferiprone, a twice-daily dosage regimen of 50 mg/kg appears appropriate, although a single daily equivalent regimen of 75 mg/kg may be as effective. However, the potential side effects do need to be considered.[58]

In the hornbill case study, the oral administration of deferiprone at 100 mg/kg q24h was found to effectively reduce the liver iron content (Figures 56.10 and 56.11).[41]

PROPHYLAXIS OF IRON STORAGE DISEASE

Low-Iron Diet

The mainstay of ISD prophylaxis is the provision of a limited iron concentration in the diet, avoiding enhancers of iron absorption and possibly adding inhibitors of iron absorption to the diet. Current diet recommendations for ISD-susceptible avian species range from 32 to 125 mg/kg iron dry matter.[55] The diet of wild birds of paradise (Paradisaeidae) is composed primarily of fruits with 15 to 30 mg/kg iron dry matter and insects with 30 to 100 mg/kg iron dry matter.[59] Studies in mynahs suggest 19 to 25 mg/kg iron dry matter.[36] Based on these results, it appears prudent to feed ISD-susceptible avian species with a diet of 25 to 50 mg/kg iron dry matter. However, these levels are probably too low for females during egg production and for growing chicks, so seasonal diet alterations may be indicated for successful managed reproduction.

In captive Raggiana birds-of-paradise *(Paradisaea raggiana)*, elevated total iron and total iron-binding capacity could be reduced by periodically removing commercial avian pellets from their diet for 30 days at 6- to 12-month intervals, reducing the diet iron content from 55 to 42 mg/kg dry matter. This method has therefore been suggested as an effective method for lowering serum iron values without the need for handling.[59]

Adult toco toucans *(Ramphastos toco)* ($n = 2$) that had previously been diagnosed with ISD by quantitative image analysis of liver biopsies showed a significant reduction in hepatocellular hemosiderin content after 8 months of being fed a diet restricted to 100 mg/kg dietary iron.[42]

Limiting iron concentration in diets of susceptible species in captivity can be challenging. In particular, additions of red meat (e.g., in the form of mouse pups that are often not considered as a staple diet item but nevertheless offered regularly to the birds) or mineral supplements[60] are problematic because of the high content of readily available iron. Limiting iron concentrations in commercially prepared complete diets also is problematic.[61,62] Domestic feedstuffs that are low in iron are relatively rare and often expensive. In addition, more traditional feedstuffs can be highly variable in iron content and monitoring their iron concentrations adds significantly to the cost.[7] This consideration is reflected in the large variety of bird diets that are commercially available, and actual iron concentrations can vary dramatically between manufacturers' information and laboratory results[35,63] and even between different batches of the same brand of food.

Inhibitors of Iron Absorption

Based on difficulties to ensure low dietary iron content, the addition of inhibitors of iron absorption has been advocated with some success. The two main groups of iron absorption inhibitors are phytates and polyphenols. Plant-derived phytates such as inositol have been shown to inhibit iron absorption in humans at very low concentrations of 2 to 10 mg/meal.[54] Polyphenols occur in vegetables, such as chili or turmeric, and in beverages such as black tea and wine as tannins.[54]

Readily available and inexpensive additives appear to successfully inhibit iron absorption from diets containing high concentrations of iron. A high-iron diet in European starlings caused an increase in the concentration of liver iron to levels similar to birds that had died of ISD. However, this same high-iron diet supplemented with inositol and tannic acid did not cause an increase in liver iron concentrations.[64] In a further study, hepatic iron concentration increased significantly in 21 European starlings fed an iron-enriched diet, but not in 20 birds that consumed the same iron-enriched diet supplemented with black tea leaves.[65]

Enhancers of Iron Absorption

Reducing dietary components that may enhance iron absorption may also have preventative value. The enhancing effect of ascorbic acid on iron absorption has been shown convincingly in humans.[54] This effect is largely due to its potential to reduce ferric to ferrous iron. In whole fruits and vegetables, the effect is probably negated by the inhibiting effect of polyphenols. In addition to the fact that muscle tissue contains heme iron, it has also been consistently shown in humans that meat, fish, or poultry have an enhancing effect on iron absorption from vegetarian meals. The nature of this

enhancement has proved elusive. However, it appears due to cysteine-containing peptides, which, similar to ascorbic acid, could reduce and chelate iron.[54] Although the addition of 10% meat supplementation and addition of ascorbic acid at 17 mg per day did not increase liver iron concentration in European starlings,[64] it remains prudent to avoid adding meat or fruits high in ascorbic acid to the diet of ISD-susceptible avian species.

In summary, chelation therapy with orally administered deferiprone is an effective and relatively easily implemented treatment of clinically diseased patients. Chelation therapy with injectable deferoxamine is also effective but more difficult to implement due to the required daily injections. Serial phlebotomies are effective in lowering body iron content but are also associated with many restricting factors. Feeding a low-iron diet in combination with adding iron-binding substances to the diet and avoiding enhancers of iron absorption will gradually lower liver iron content but is mainly effective for subclinical cases or preventive purposes and not for the treatment of clinically diseased avian patients. It is important to be aware of increased iron requirements during times of reproduction and to prudently avoid severe iron restriction during this period.

THE HORNBILL CASQUE IN HEALTH AND DISEASE

Shangzhe Xie

The hornbill casque is a prominent organ that presents a unique focus for veterinary attention in hornbills. It is important to understand the hornbill casque in health and disease so that appropriate diagnostic and therapeutic interventions can be performed when required.

THE HORNBILL CASQUE IN HEALTH

The casque is a conspicuous bony outgrowth of the skull that is present in several taxa of birds.[66] The most well-known families of birds with casques are Casuariidae and Bucerotidae.[66,67] The shapes, sizes, and colorations of the 57 extant hornbill species vary from a simple ridge in *Tockus* species to elaborate recurved horns in *Anthracoceros* species.[68,69] The proposed functions of the casque include structural beak reinforcement for behaviors such as aerial jousting,[70] visual display to demonstrate social status or sexual maturity,[68,69] and acoustic amplification of vocalizations.[71]

In all species of hornbills except the helmeted hornbill *(Rhinoplax vigil)*, the casque is an air-filled cavity enclosed in a very thin layer of cancellous bone.[68,69,72] The bony outgrowth is covered by cornified rhamphotheca, which is often colorful and defines its visible outline.[66,67] A division of the paranasal sinus, known as the casque sinus and unique to hornbills, has been demonstrated by advanced imaging in six hornbill species.[67] Further studies are needed to demonstrate the presence of the casque sinus in other hornbill species, but it may be a route for neoplastic cells or infectious agents to extend into deeper parts of the skull or paranasal sinus system.[67]

Development of the Hornbill Casque

The casque originates from the ridge (culmen) of the maxillary rhamphotheca, which is highly vascular and enlarges with age and sexual maturity.[68,69] The development of pneumatization of hornbill casques is not well studied, but it is hypothesized in other avian species that it is caused by diverticula of the antorbital or frontal-ethmoidal sinus and develops late in ontogeny, as pneumatization is absent in the skulls of immature birds.[66]

The development of the beak and casque of hornbills generally follows the maturation of the chick, and the timeline appears consistent for both Asian and African hornbill species. The growth series of an Asian species is represented by a rhinoceros hornbill *(Buceros rhinoceros)* and an African species is represented by a Von der Decken's hornbill *(Tockus deckeni)* (Figures 56.12 and 56.13).

THE HORNBILL CASQUE IN DISEASE

Common Causes of Casque Injury, Disease, and Problems

Reports of diseases of the casque are uncommon but include infection,[73] traumatic injury,[74] and squamous cell carcinoma in great hornbills.[75] In this author's experience, casque diseases and injuries are uncommon. However, communications with other veterinarians in the Southeast Asia region, where great hornbills are more commonly kept in captivity, suggest that external casque lesions similar to those that were reported in squamous cell carcinoma cases occur more frequently than the literature records. Definitive diagnoses could not be obtained for many of these cases as they were not conclusively diagnosed.

FIGURE 56.14 Lateral head radiograph of a normal adult male trumpeter hornbill *(Bycanistes bucinator)*.

Casque Diagnostic Imaging

Lateral (Figure 56.14) and dorsoventral radiographic views of the casque can be easily obtained with physical restraint of the patient. The radiographic anatomy of the casque has been described in detail,[2] but the amount of diagnostic information obtained from radiographs is usually limited. Obvious casque masses can usually be visualized on radiographs,[73,75,76] but this imaging modality does not allow differentiation between infectious and neoplastic causes of the mass.

Multislice advanced medical imaging data, particularly computed tomography (CT) (Figure 56.15) and MRI, can more accurately reflect anatomical details of the scanned region than radiographs and the images obtained can be converted to 3D volumetric models (see Chapter 2).[77] A biopsy of any masses (Figure 56.16) found can also be obtained under CT guidance.[76] Nonguided samples obtained for cytology, histopathology, and culture very frequently only obtain surface necrotic tissue, which are of limited diagnostic value. Based on these patient-specific 3D models, customized surgical tools can be created and precisely fitted to the anatomy, allowing improved surgical planning that translates to superior surgical outcomes.[78–80]

Casque Repair and Prosthetic Options

Sealing the casque after sinusotomy has been associated with infection.[73] It has been demonstrated that such infections can heal successfully by managing an open wound with extensive lavage.[73] In this instance, the casque healed by granulation initially, but eventually repneumatized.[73] Other repair techniques exist and are similar to beak repair techniques described (see Chapter 31).

In cases of squamous cell carcinoma where radical casque resection is the preferred treatment, production of a suitable casque prosthesis has historically been challenging.[81] However, 3D-printing technology has provided an improved way to produce casque prostheses.[76] The best way to preserve the

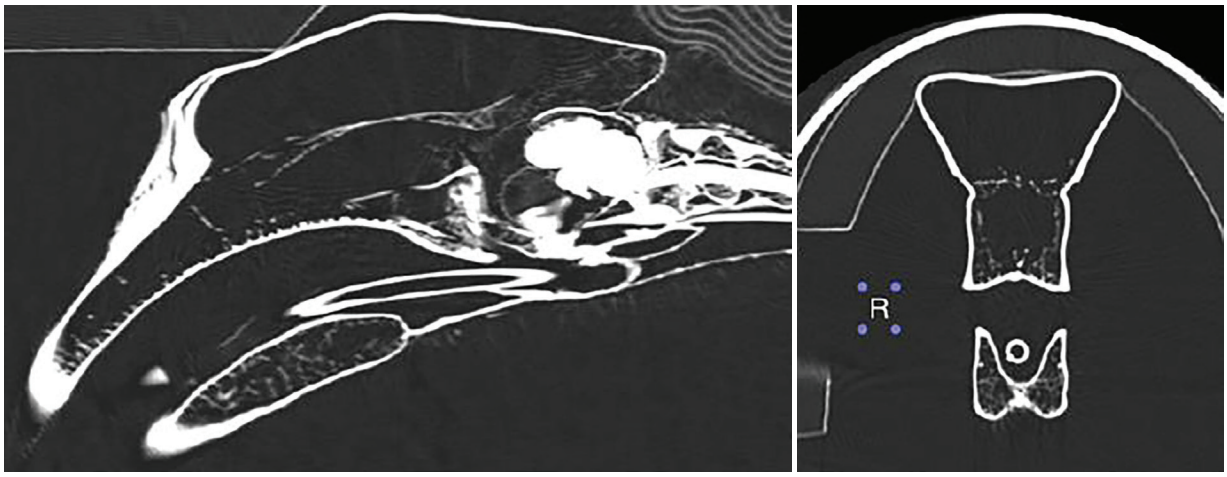

FIGURE 56.15 CT scan images of a normal adult male great hornbill *(Buceros bicornis)*.

patient's aesthetics, retain as many original acoustic properties as possible, and minimize changes to the patient's vocalizations and balance was for the shape of the artificial 3D-printed prosthesis (Figures 56.17 and 56.18) to be identical in shape to the original beak and casque.[76] This approach can be made using CT images, which also allow production of a cutting guide (Figures 56.17 and 56.18) that fits the anatomy of the dorsal maxillary beak and casque and clearly identifies the planned surgical margins during surgery.[76] The 3D-printed prosthesis can be affixed to the maxillary beak using 2.7-mm cortical screws (DePuy-Synthes, Solothurn, Switzerland) or similar around the perimeter of the surgical margins.[76] Dental acrylic can be used to seal any remaining gaps between the prosthesis and the casque and beak (Figure 56.19), but this does not usually add any further stability to the prosthesis.[76] Such a technique (see Chapter 31) performed personally by the author and several other veterinary teams for separate cases did not result in any postoperative complication, and in the first case, no recurrence of the tumor had occurred more than 5 years after the surgery.[76] In this case, the keratin was found to have completely grown over the surgical defect and the prosthesis was no longer needed after it fell off 20 months after surgery (Figure 56.20). Follow-up radiation therapy or topical chemotherapy, which had limited success from previous reports,[81] was also not required with this technique. The success is likely due to the larger surgical margins used than in previous cases, where a suitable prosthesis could not be produced to cover a large postsurgical defect in the casque.

APPENDIX 1

Table of Common Drugs and Approximate Doses*

James W. Carpenter • Michelle G. Hawkins • Heather W. Barron • Rachel Baden

TABLE 1

Antibacterial Agents

Agent	Dosage	Species/Comments
Amikacin	7–20 mg/kg SC, IM, IV q8–12h	Most species; may cause myositis with IM injection; least nephrotoxic of the aminoglycosides, but renal toxicosis has been demonstrated in some species at 10 mg/kg—after 11 days; uric acid levels may be abnormal for up to 7 days after cessation; maintain hydration during use
	15 mg/kg IM q12h, IV q8h[168]	Blue-fronted Amazon parrots/PD
	15–20 mg/kg IM q8–12h[148]	Cockatiels/PD
	15–20 mg/kg IM q8h[44]	Chickens
	15–20 mg/kg IM q24h (can be divided over 2×–3× a day)[15]	Red-tailed hawks; dose remained above MIC for >12 hours for most isolates examined
	5.3 mg/kg IV[149]	Chicken/regional limb perfusion
	528 mg/L water	Ratites/egg dip
	3 g/40 packet bone cement	PMMA bead formation (1:14 ratio); same dose for all aminoglycoside beads
Amoxicillin/clavulanate (Clavamox, Pfizer)	125–250 mg/kg PO q8–12h	Most species, including pigeons, psittacines, and raptors
	125 mg/kg PO q8h[134]	Amazon parrots; area under curve increased compared to humans
	125 mg/kg PO q12h[171]	Chickens/PK; insufficient to achieve target plasma levels, no amoxicillin detected in eggs
	500 mg/L drinking water	Chickens/PD
Amoxicillin sodium	50–250 mg/kg IM, IV q8–12h	Most species, including bustards, pigeons, passerines, soft bills, and gram-positive and gram-negative bacteria
Amoxicillin trihydrate	55–200 mg/kg PO, SC, IM, IV, q4–12h	Most species/broad-spectrum bactericidal penicillin antibiotic; minimal activity for common gram-negative infections of birds; relatively low availability after oral administration
	150 mg/kg SC, IM q24h × 5 days (administer q48h with long-acting preparation)	Pigeons
	200–1500 mg/L drinking water	Pigeons, canaries, waterfowl
	1500–4500 mg/L drinking water	Psittacines
	300–600 mg/kg soft feed	Canaries, psittacines

Continued

*Although the authors attempted to verify dosages contained in this formulary, errors in the original sources or in the preparation of this chapter may have occurred. All users of this reference, therefore, should empirically evaluate all dosages to determine that they are reasonable before use. The publisher assumes no responsibility and makes no warranty with respect to results obtained from the uses or dosages listed, for any misstatement or error, negligent, or otherwise, contained in this chapter. In addition, the authors do not necessarily endorse specific products or dosages reported in this formulary. Also, the listing of a drug or commercial product in this chapter does not indicate approval by the Food and Drug Administration or the manufacturer for use in exotic animals. Drug dosages are listed in ascending order; feed and water dosages are listed last.
Most of the avian formulary information has been modified with permission from Carpenter JW, editor: *Exotic animal formulary*, ed 5, St. Louis, 2017, Saunders.

TABLE 1

Antibacterial Agents—cont'd

Agent	Dosage	Species/Comments
Ampicillin sodium	50–150 mg/kg IM q6–12h	Most species/PD
	150–200 mg/kg PO q8–12h	Amazon parrots/PD; therapeutic levels not achieved in one species at this dosage
	528 mg/L drinking water	Pigeons/PD; *Streptococcus bovis*
Ampicillin trihydrate	15–25 mg/kg SC, IM q12h	Ratites, cranes, raptors/PD
	100 mg/kg PO, IM q4–12h	Most species
	150–175 mg/kg PO, q8–12h[47]	Amazon parrots, oral dosing resulted in prolonged (up to 10 hours) but less consistent plasma levels compared to IM dosing
	1000–2000 mg/L drinking water	Galliformes, canaries/flock use
	2000–3000 mg/kg soft feed	Canaries/aviary use
Ampicillin/sulbactam (Unasyn, Pfizer)	200–300 mg/kg IM, IV q8h[54,55]	Poultry/PD
Azithromycin (Zithromax, Pfizer)	10–40 PO q24–48h	Most species/PD in cockatiels and macaws; found to be effective in eliminating *Chlamydia psittaci* infections after 21 days
	10 mg/kg PO q48h[21]	Blue-and-gold macaws/PK
	20 mg/kg PO, IM q72h[1]	Chicken/PK
	43 mg/kg PO q24h[160]	Ring-necked doves/PD, combined use with ethambutol (30 mg/kg PO q24h) and rifampin (45 mg/kg PO q24h) for 180 days; efficacy against *Mycobacterium avium* appeared poor
Azithromycin sustained-release granules (Zetamax, Pfizer)	35 mg/kg PO loading dose followed by 25 mg/kg PO q12h[207]	Pigeons/PK
Carbenicillin (Geocillin, Roerig; Pyopen, SmithKline Beecham)	100–200 mg PO, IM, IV q6–12h	Most species
Cefadroxil	100 mg/kg PO q12h	Most species
Cefazolin	25–75 mg/kg PO, IM, IV q12h	Most species
Cefotaxime (Claforan, Hoechst-Roussel)	50–100 mg/kg IM, IV q8–12h	Most species
Cefovecin (Convenia, Pfizer)	10 mg/kg SC, IM, IV q1h	Pigeons, chickens/PD; not recommended for use in birds due to short half-life; cannot be used q14d as in dogs and cats
Cefoxitin	50–100 mg/kg IM, IV q6–12h	Most species
Ceftazidime	50–100 mg/kg IM, IV q4–8h	Most species
Ceftiofur crystalline-free acid (Excede, Pfizer)[a]	10–20 mg/kg IM q3–5d[95,103,159,193,200]	Red-tailed hawks/PD; American black ducks/PD; helmeted guineafowl/PD; cattle egrets/PK; American flamingos/PK
	10 mg/kg IM q60–110h[158]	Bald eagles/PK
	20 mg/kg IM q80–160h[158]	Bald eagles/PK
	50 mg/kg IM once[187]	Ring-necked doves/PK; plasma concentrations remained above MIC for 108 hours
Ceftiofur sodium (Naxcel, Pfizer)[a]	10–50 mg/kg IM q4–12h	Most species/PD in cockatiels and one species of Amazon parrot
	2 mg/kg IV or IO[107]	Chickens/regional limb perfusion
Ceftriaxone	75–100 mg/kg IM q4–8h	Most species/PD in chickens
Cephalexin	50–125 mg/kg IM, PO q6–12h	Most species/PD mostly in poultry
Cephalothin	100 mg/kg IM, IV q6–8h	Most species/PD in poultry
Chloramphenicol palmitate (oral suspension)[a]	25–50 mg/kg PO q8h	Most species
Chloramphenicol succinate[a]	22 mg/kg IM, IV q3h	Ducks (PD), raptors
	50 mg/kg IM q6–12h	Most species; PD in macaws, conures, peafowl, eagles, geese
	200 mg/kg IM q12h × 5 days	Budgerigars/PD
Chlortetracycline (Aureomycin Soluble Powder, Cyanamid)	15–20 mg/kg PO q8h	Pigeons/PD
	100 mg/kg PO q6h	Raptors
	0.5%–1% pellets × 30–45 days	Psittacines/*Chlamydia*; reduce calcium in diet to 0.7%
	5000 mg/kg soft feed × 45 days	Chickens, turkeys/PD; medication of feed and water required to reach therapeutic level
	2500 mg/L drinking water	Most species
Ciprofloxacin (Cipro, Bayer)[a]	15–40 mg/kg PO, IM, IV q12h	Most species
	50 mg/kg PO q12h	Raptors/PD
	80 mg/kg PO q24h	Most species/*Mycobacterium*; use in combination with other agents

TABLE 1

Antibacterial Agents—cont'd

Agent	Dosage	Species/Comments
Clarithromycin (Biaxin, Abbott)	10–85 mg/kg PO q24h	Most species/*Mycobacterium*; allometrically scaled
Clindamycin	25–50 mg/kg PO q8–12h	Most species
	100 mg/kg PO q6h[111]	Pigeons/PD
	100–150 mg/kg PO q12h	Raptors; osteomyelitis
Clofazimine (Lamprene, Novartis)	1–12 mg/kg PO q12–24h	Most species/*Mycobacterium*; use in combination with other agents
Cloxacillin	100–250 mg/kg PO, IM q12–24h	Most species, including raptors; recommended for treating pododermatitis
Danofloxacin mesylate (A180, Pfizer)[a]	5–10 mg/kg PO, SC, IM, IV[28,38]	Most species
	15 mg/kg IM[165]	Californian brown pelicans/PK
Doxycycline (Vibramycin, Pfizer)	25–50 mg/kg PO q12–24h	Cockatiels/PD; *Chlamydia*; treatment for 21 and 45 days both effective; may cause regurgitation; use low end of dose range for macaws and cockatoos
	400–800 mg/L drinking water (make fresh daily)	Waterfowl, budgerigars (PD); treatment for 21 days in cockatiels with spirochete bacteria
	300 mg/kg diet (wet weight) × 42 days[62]	Cockatiels/PD; doxycycline was added to soybean oil and then mixed with a pelleted diet formulated with reduced calcium (to reduce doxycycline chelation) and a low-fat content
	1000 mg/kg feed	Large psittacines on dehulled seed (PD), macaws on corn (PD), canaries, large psittacines on soft feed (10 mg/mL syrup mixed into 29% kidney beans, 29% canned corn, 29% cooked rice, and 13% dry oatmeal cereal)
Doxycycline (Vibravenös, Pfizer)	50–100 mg/kg SC, IM q5–7d × 5–7 doses	Most species; PD in pigeons and houbara bustards
Doxycycline hyclate (Vibramycin injection, Pfizer)	25–50 mg/kg slow bolus IV q24h × 3 days	Psittacines (cardiovascular collapse associated with the propylene glycol carrier can occur after rapid IV injection)
	20 mg/kg PO, IV q24h × 3 days[201]	Laying hens/PK
	75–100 mg/kg SC, IM q5–7d	Pigeons/PD
Doxycycline (Doxirobe gel, Pharmacia)	Topical	Most species/apply to beak or pododermatitis lesions; use in conjunction with debridement; antibiotic is released for 28 days
Enrofloxacin[a]	—	Injectable formulation is highly alkaline and may cause tissue necrosis and pain; repeated IM injections are not recommended; no detectable effect on cartilage in day-old chicks; appears stable when compounded and stored at room temperature; may be administered in some food items
	7.5–9.5 mg/kg IM, IV q24h[195]	Crested caracaras/PD
	10–15 mg/kg PO, SC, IM q12h[33,192]	Most species/PD
	15 mg/kg PO, SC q24h[131]	Caribbean flamingos/PK
	15 mg/kg PO, IM, IV q12h	Raptors/PD; IV administration in owls may result in weakness, tachycardia, and vasoconstriction
	15–30 mg/kg PO, SC, IM q12–24h	Most species/PD for pulse dosing in some species
	50 mg/L drinking water	Chickens, turkeys/PD
	100–200 mg/L drinking water	Psittacines, pigeons/PD
	200–750 mg/mL drinking water	Psittacines/PD
	250–1000 mg/kg feed	Passerines; psittacines/PD
	50 mg/kg via nebulization × 4 hours (day 1, AM), then 25 mg/kg × 4 hours/day × 4 days	Muscovy, Pekin ducklings/*Riemerella (Pasteurella)*
	0.2 mg/mL saline, flush q24h × 10 days	Raptors/nasal flush
Erythromycin	10–20 PO, IM q12–24h	Most species; IM injection can cause muscle necrosis
	100 mg/kg PO	Pigeons/PD
	100–1500 mg/L drinking water	Most species; pigeons/PD

Continued

TABLE 1

Antibacterial Agents—cont'd

Agent	Dosage	Species/Comments
Ethambutol (Myambutol, Lederle)	10–30 mg/kg PO q12–24h	Most species/*Mycobacterium*; use in combination with other agents
Florfenicol[a]	30 mg/kg PO q12h[184,185]	Geese, ducks/PK
Gentamicin	2.5–5 mg/kg IM q8–12h	Most species; nephrotoxic; should be well hydrated; caution at higher doses
	5–10 mg/kg IM q8–12h	Cockatiels/PD
	5–10 mg/kg IM q4–6h	Pigeons, quail/PD
	2–3 drops ophthalmic solution intranasal q8h	Most species
Isoniazid	5–30 mg/kg PO q12–24h	Most species/*Mycobacterium*; should be used in combination with other drugs
Kanamycin (Kantrim, Fort Dodge)	10–20 mg/kg IM q12h	Most species
	13–65 mg/L drinking water	Most species; make fresh daily
Lincomycin	0.25–0.5 mL intraarticular q24h	Raptors
	25–50 mg/kg PO q12h	Most species
	50–100 mg/kg PO, IM q12–24h	Psittacines, raptors
Lincomycin/spectinomycin (LS-50 Water Soluble, Upjohn; Linco-Spectin 100 Soluble Powder, Upjohn)	50 mg/kg PO q24h	Most species
	528 mg/L drinking water	Turkey poults/PD; *Mycoplasma* airsacculitis
	750 mg/L drinking water × 3–7 days	Waterfowl
Marbofloxacin (Zeniquin, Pfizer)[a]	2–2.5 mg/kg PO q24h[74,205]	Broiler chickens and Muscovy ducks/PD
	2.5–5 mg/kg PO q24h	Blue-and-gold macaws/PD
	2–3 mg/kg IV, IO q24h	Raptors/PD
	3–12 mg/kg PO q24h	Turkeys/PD
	5 mg/kg IM, IV	Ostriches/PD
	10–15 mg/kg IV q24h[67]	Ducks/PD
	10–15 mg/kg PO, IM q12–24h	Raptors, bustards/PD
Meropenem (Merrem, Abbott)	175 mg/kg IM q24h	Pigeons/PD; broad-spectrum carbapenem antibiotic, penetrates most tissues and fluids
Metronidazole[a]	10–50 mg/kg PO q12–24h	Most species
Minocycline	10–15 mg/kg PO q12h	Penguins, raptors
	5000 mg/kg feed	Parakeets/use as antibiotic impregnated millet
Neomycin	Topical q6–12h	Use is generally limited to topical formulations for skin, eyes, and ears and, occasionally, oral treatment of enteric infections; not absorbed from GI tract
	10 mg/kg PO q8–12h	Most species
	80–264 mg/L drinking water	Waterfowl, Galliformes
	70–220 mg/kg feed × 14–21 days	Waterfowl, Galliformes/*Clostridium*, necrotizing enteritis
Norfloxacin (Noroxin, Merck; Vetriflox 20% Oral Solution, Lavet Ltd)[a]	—	Fluoroquinolone; not approved for use in food-producing birds in the United States; administration of the total daily dose to chickens over 2–4 hours (pulse dosing) has been recommended
	8 mg/kg PO q24h	Chickens/PD
	10 mg/kg PO q24h	Chickens, geese/PD
	10 mg/kg PO q6–8h	Turkeys/PD
	15 mg/kg in water over 2–4 hours	Turkeys/PD
	100 mg/L drinking water × 5 days	Chickens/PD
Novobiocin sodium	15–30 mg/kg PO q24h	Poultry/effective against some gram-positive cocci
	220–385 mg/kg feed	Poultry, waterfowl
Orbifloxacin (Orbax, Schering-Plough)[a]	15–20 mg/kg PO q24h[93]	Japanese quail/PD
Ormetoprim-sulfadimethoxine (Primor, Pfizer)	60 mg/kg PO q12h	Pigeons
	475–951 mg/L drinking water × 7–10 days	Pigeons
	200–800 mg/kg feed	Waterfowl/colibacillosis

TABLE 1

Antibacterial Agents—cont'd

Agent	Dosage	Species/Comments
Oxytetracycline	—	IM administration may cause muscle irritation or necrosis; may be useful in treating *Chlamydophila*, fowl cholera; products or foods containing Al, Ca, Mg, Fe reduce or alter absorption; outdated tetracycline is nephrotoxic
	2 mg/mL nebulization q4–6h	Parakeets/requires ultrasonic nebulizer; therapeutic concentrations of antibiotic were present in lung and trachea
	5 mg/kg SC, IM q12–24h	Chicken chicks/PD
	10 mg/kg IM q24h[69]	Chickens/PK
	20 mg/kg IM q72h (long-acting formulation)[69]	Chickens/PK
	16 mg/kg IM q24h	Great horned owls/PD
	23 mg/kg IV q6–8h or 43 mg/kg IM q24h	Pheasants/PD
	50–100 mg/kg SC, IM q2–3d	Cockatoos (PD), passerines
	58 mg/kg IM q24h	Amazon parrots/PD
	2500 mg/L drinking water and 2500 mg/kg feed	Chickens (PD), turkeys (PD), waterfowl/simultaneous medication of feed and water required to reach therapeutic level
	300 mg/kg soft feed	Psittacines
Penicillin	50,000 IU/kg IM	Waterfowl/*Erysipelas*, new duck disease
	8 g/40 g packet bone cement	PMMA beads (ratio 1:5)
Penicillin benzathine/procaine	200 mg/kg IM q24h	Most species: anecdotal reports suggest should not be used in birds <1 kg BW because of possible toxic effects
Penicillin G	6 mg/kg IV	Ostriches, emus/PD; rapidly eliminated; small volume of distribution
Piperacillin sodium	—	Extended-spectrum penicillin; not available as a veterinary product in the United States; see piperacillin/tazobactam
	100 mg/kg IM q4–6h	Red-tailed hawks, great horned owls/PD
	200 mg/kg IM q8h	Budgerigars (PD), raptors
	0.02 mL (4 mg) in macaw eggs; 0.01 mL (2 mg) in small eggs	Eggs/inject 200 mg/mL solution into air cell on days 14, 18, and 22
Piperacillin(P)/tazobactam(t) (Zosyn, Tazocin, Wyeth)	(P) 87 mg/kg + (t) 11 mg/kg IM q3–4h[22]	Hispaniolan Amazon parrots/PD
Rifabutin (Mycobutin, Pharmacia)	15–45 mg/kg PO q24h	Most species including passerines/*Mycobacterium*; use in combination with other agents
Rifampin	10–20 mg/kg PO q12–24h	Most species/*Mycobacterium*; use with other agents; may cause/be associated with hepatitis, CNS signs, depression, and vomiting
	45 mg/kg PO q24h	
Silver sulfadiazine	Topical q12–24h	Most species/burns, ulcers; Amazon foot necrosis; bandage application preferred
Streptomycin (Streptomycin Sulfate, Roerig)	—	May be nephrotoxic or neurotoxic; not recommended; consider amikacin as an alternative; *Mycobacterium*; use in combination with other agents
	20–50 mg/kg PO, IM q12–24h	Most species; chickens/PD
Sulfadimethoxine (Albon, Pfizer)	25–55 mg/kg PO q24h × 3–7 days	Raptors; loading dose at higher end × 1 day
	50 mg/kg PO q24h	Cranes
	330–400 mg/L drinking water on day 1 followed by 200–265 mg/L × 4 days	Pigeons
Tetracycline	50 mg/kg PO q8h	Most species, including passerines
	200–250 mg/kg PO q12–24h	Most species/gavage
	40–200 mg/L drinking water	Most species, including game birds
	100–600 mg/kg feed	Game birds
Tiamulin (Denagard, Novartis)	12.5 mg/kg PO × 3 days	Poultry/intestinal spirochetosis
	25–50 mg/kg PO q24h	Most species; bacteriostatic antibiotic; effective against *Mycoplasma*
Ticarcillin/clavulanate (Timentin, Smith-Kline Beecham)	100–200 mg/kg IM, IV q12h	Most species; extended-spectrum penicillin; very poor absorption if injectable given orally
Tilmicosin (Micotil 300 Injection, Provitil-powder and Pulmotil AC-liquid, Elanco)	30 mg/kg PO q24h	Poultry/PD
	100–500 mg/L drinking water × 5 days	Poultry chicks/*Mycoplasma*; macrolide; handle with caution; potentially fatal to humans

Continued

TABLE 1

Antibacterial Agents—cont'd

Agent	Dosage	Species/Comments
Tobramycin	0.25–0.5 mL intraarticular flush q24h × 7–10 days	Raptors/septic arthritis
	2.5–5 mg/kg IM q8–12h	Most species; neurotoxicity or nephrotoxicity may develop
Trimethoprim-sulfadiazine (Tribrissen, Schering-Plough; Septra, Monarch)	12–60 mg/kg PO q12h	Raptors/useful for sensitive infections in neonates
	20 mg/kg SC, IM q12h	Psittacines
	30 mg/kg PO, IM, IV q12h	Ostriches/PD
	30 mg/kg PO q8h	Psittacines; combine with pyrimethamine for treatment of sarcocystosis
	107 mg/L drinking water	Galliformes
Trimethoprim/sulfamethoxazole (Bactrim, Roche; Septra, Burroughs Wellcome)	48 mg/kg PO, IM q12h	Raptors
	60 mg/kg PO q24h	Pigeons
	100 mg/kg PO q12h	Most species, including psittacines; reduce dose if regurgitation occurs
	360–400 mg/L drinking water	Most species, including pigeons
	400 mg/kg feed	Geese
Tylosin (Tylan, Elanco)	15–30 mg/kg IM q6–12h	Most species; effective against gram-positive bacteria, *Mycoplasma*, *Chlamydia*, and *Pasteurella*; very irritating to muscles when administered IM
	50 mg/kg PO q24h	Passerines, pigeons
	60 mg/kg/day PO[45]	Muscovy ducks/PD against *Mycoplasma anatis*
	50 mg/L drinking water	Most species
	250–1000 mg/L drinking water	Most species/*Mycoplasma*

[a]These drugs are banned in food-producing species in the United States as well as some other countries. Use with caution and follow local laws regarding administration to food animals.

AM, ante meridiem, in the morning, *BW,* Body weight; *CNS,* central nervous system, *GI,* gastrointestinal, *IM,* intramuscular; *IV,* intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PMMA,* polymethyl methacrylate; *PO,* oral; *SC,* subcutaneous.

TABLE 2

Antifungal Agents

Agent	Dosage	Species/Comments
Amphotericin B	—	Fungicidal; lipid-based amphotericin B products are now available that have less toxicity than conventional desoxycholate form; *Macrorhabdus ornithogaster* (avian gastric yeast); preferred IV agent for aspergillosis; intratracheal administration for syringeal aspergilloma may cause tracheitis; potentially nephrotoxic; resistance may develop
	1.5 mg/kg IV q8h × 3–7 days	Most species
	1 mg/kg intratracheal q8–12h, dilute to 1 mL with sterile water	Psittacines, raptors/aspergillosis
	1 mg/kg intratracheal q12h × 12 days, then q48h × 5 weeks	Raptors/syringeal aspergilloma
	100–109 mg/kg PO by gavage q12h × 10–30 days	Budgerigars/avian gastric yeast; compound in simple syrup
	0.05 mg/mL sterile water	Most species/nasal flush
	0.2 mL PO q12h × 10 days	Budgerigars/avian gastric yeast; use IV formulation (5 mg/mL)
	0.25–1 mL PO q24h × 4–5 days	Raptor neonates/candidiasis; not absorbed from alimentary tract
	1000 mg/L drinking water × 10 days	Budgerigars/avian gastric yeast
	Topical	Apply 10% solution to oropharynx
	7 mg/mL saline q12h	Most species/nebulization × 15 minutes
Amphotericin B (3% cream)	Topical to affected area q12h	Most species/mycoses
Amphotericin B (A)/proteolytic nasal flush (P)	Nasal flush (A) 1 mg/kg + (P) 0.2–0.4 mL diluted in 20 mL saline q24h	Uses a commercial neomycin-chymotrypsin-trypsin-hydrocortisone ointment (Kymar, Schering-Plough); 10 mL per naris (flushed vigorously in small amounts); consider compounding without hydrocortisone to avoid any immunosuppressive side effects
Clotrimazole	—	Broad-spectrum antifungal agent; inhibits the growth of pathogenic yeasts such as *Candida albicans*; used commonly as adjunctive therapy for aspergillosis; administer via air sac, intratracheally, nebulization, or topically
	2 mg/kg intratracheal q24h × 5 days	Psittacines/syringeal aspergilloma; apply with catheter or endoscope directly into syrinx during anesthesia
	10 mg/mL saline flush	Most species/effective against *Aspergillus* at sites that can be flushed
	1% solution	Nebulization × 30–60 minutes
Enilconazole emulsion	6 mg/kg PO q12h	Eclectus parrots/glossal candidiasis
	1 mg (0.5 mL)/kg intratracheal of a 1:10 dilution q24h	Falcons/aspergillosis
	200 mg/L drinking water	Canaries/cutaneous dermatophytosis
	Topical 1:10 dilution q12h	Raptors/cutaneous aspergillosis, candidiasis
	Topical or intratracheal 1:10–1:100 dilution	Psittacines/aspergillosis, candidiasis
	0.1 mL/kg in 5 mL sterile water, nebulize × 30 minutes, 5 days on, 2 off, up to 3 months	Raptors/aspergillosis
Fluconazole (Diflucan, Pfizer)	—	Fungistatic; penetrates well into brain, cerebrospinal fluids, and eyes; *Candida*; only indicated if topical treatment (i.e., nystatin) is not feasible; water-soluble; safest therapeutic index of the azoles; may be ineffective against aspergillosis; death observed in budgerigars at 10 mg/kg PO q12h (this dose was also ineffective against avian gastric yeast with *Macrorhabdus*); compounded oral suspension stable for 14 days when refrigerated
	2–6 mg/kg PO q12–24h	Most species
	5 mg/kg PO q24h, 10 mg/kg PO q48h[151]	Cockatiels/PD
	5–15 mg/kg PO q12h × 14–60 days	Most species
	8 mg/kg PO q24h × 30 days	Psittacines/cryptococcosis
	20 mg/kg PO q48h	Psittacines/PD; mucosal, systemic yeast infections
	100 mg/L in drinking water[151]	Cockatiels/PD
	100 mg/kg soft food	Gouldian finches/candidiasis

Continued

TABLE 2

Antifungal Agents—cont'd

Agent	Dosage	Species/Comments
Flucytosine (Ancobon, Roche)	—	Fungistatic agent; penetrates well into CNS; used prophylactically in raptors (especially falcons) and waterfowl to prevent aspergillosis; may be administered as adjunctive treatment; about 50% of *Aspergillus* strains are resistant; toxicity is low; however, adverse effects may include gastrointestinal effects, hepatotoxicity, and bone marrow depression
	20–75 mg/kg PO q6–12h	Most species/generalized yeast or fungal infections
	75 mg/kg q12h × 5–7 days, then q24h × 14 days	Raptors/prophylaxis for prevention of aspergillosis
	75–120 mg/kg PO q6–12h	Most species/aspergillosis
	50–250 mg/kg feed	Psittacines, mynah birds
Griseofulvin	10 mg/kg PO q12h	Pigeons/dermatophytosis; gavage
	30–50 mg/kg q24h in drinking water	Ostriches/mycotic dermatitis
Itraconazole (Sporanox, Janssen)	—	Most species/systemic mycoses, superficial candidiasis, dermatophytosis; fungistatic; maximal oral bioavailability when taken with a full meal; commercially available suspension is recommended as a first choice; do not use compounded formulations because bulk drug is not bioavailable or stable
	2.5–5 mg/kg PO q24h	Grey parrots/anorexia, depression, and toxicity reported at higher doses in this species
	5–10 mg/kg PO q24h	Blue-fronted Amazon parrots/PD; aspergillosis; 10 mg/kg is required to achieve therapeutic concentrations in poorly perfused tissues
	5–10 mg/kg PO q12–24h × 10–14 days, then q48h	Raptors/aspergillosis prophylaxis
	5–10 mg/kg PO q12h	Passerines, waterfowl
	20 mg/kg PO q24h	Penguins/PD
	26 mg/kg PO q12h	Pigeons/PD; fungicidal levels achieved in respiratory tissue; further toxicologic studies required
	200 mg/kg feed up to 100 days	Gouldian finches/PD; dermatomycoses; beads from capsules were mixed with small amount of oil and seed
Itraconazole (Itrafungol, Elanco)	10 mg/kg PO q24h[161]	Lesser flamingos/PK
	20 mg/kg PO[206]	African penguins/PK
Ketoconazole (Nizoral, Janssen)	—	Most species/systemic mycoses (e.g., aspergillosis), candidiasis; fungistatic; less toxic than amphotericin B; more toxic than itraconazole; may be associated with potentially fatal hepatotoxicity; 20 mg/kg may cause regurgitation (discontinue for 1–2 days, then restart)
	30 mg/kg PO q12h × 7–14 days	Amazon parrots/PD
	30 mg/kg PO q12h × 7–30 days	Pigeons (PD), raptors/prophylactic in raptors for aspergillosis
	60 mg/kg PO q12h	Raptors/PD (common buzzard); aspergillosis
	200 mg/L drinking water, nectar, or soft feed × 7–14 days	Canaries, hummingbirds, Gouldian finches/dissolve crushed tablet in ½–1 tsp vinegar
Miconazole	—	Fungistatic; inhibits the growth of *Candida albicans*, *Malassezia*, and dermatophytes; injectable miconazole is not available in the United States
	5 mg/kg intratracheal q12h	Psittacines/10 mg/mL solution diluted with saline; syringeal mycoses
	10–20 mg/kg IM, IV q8–24h	Raptors, psittacines
	Topical to affected areas q12h	Cutaneous fungal infections; used in conjunction with oral itraconazole
Nystatin	—	Drug of choice for treatment of candidiasis; not systemically absorbed across intact gastrointestinal tract; oral lesions must be treated by direct contact with medication; when treating neonates, administer separately from formula to maximize concentration and contact time
	20,000–100,000 U PO q12–24h	Raptors, pigeons
	300,000–600,000 U/kg PO q8–12h	Most species
	Topical q6h	Hummingbirds/candidiasis; direct application using a cotton swab
	100,000 U/L drinking water	Canaries, finches

TABLE 2

Antifungal Agents—cont'd

Agent	Dosage	Species/Comments
Pimaricin (Natamycin, Alcon)	1 drop in affected eye q8h	Lovebirds/macrolide antifungal; keratomycosis
Silver sulfadiazine	Topical to affected areas q12–24h	Most species/bandage application preferred
Terbinafine	—	Fungicidal; questionable therapeutic potential for the treatment of aspergillosis in avian species; higher dose or use in combination with itraconazole may be more effective
	10–30 mg/kg PO q12–24h	Most species
	15 mg/kg PO q24h	Penguins/PD
	22 mg/kg PO q24h	Raptors/PD
	60 mg/kg PO q24h[52]	Amazon parrots/PD
	60 mg/kg PO q6–8h[155]	Shelducks/PK
Voriconazole (Vfend, Pfizer)	—	Most active drug against *Aspergillus*; some strains resistant; dose extrapolation difficult between species; PO and IV solutions available; may need to adjust dose for long-term treatment to maintain therapeutic concentrations; compounded suspensions stable up to 30 days at room temperature
	5 mg/kg PO q24h[99,136]	Magellanic penguins/PK, African penguins/PK
	10 mg/kg PO, IV q12h	Chickens/PD
	10 mg/kg PO q12h or 20 mg/kg q24h	Pigeons/PD
	10 mg/kg PO q8h[70]	Hawks/PD; more frequent dosing (e.g., up to q8h) may be necessary to maintain target concentrations during prolonged therapy
	12–18 mg/kg PO q12h	Grey parrots/PD
	12.5 mg/kg IM q24h[4]	Falcons/PK
	15 mg/kg PO q24h[137]	Red-tailed hawks/PK
	18 mg/kg PO q8h	Amazons/PD
	40 mg/kg PO q24h	Quail/PD
	20 mg/kg IV, PO q8–12h[106]	Ducks/PD

IM, Intramuscular; *IV,* Intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PO,* oral.

TABLE 3

Antiviral and Immunomodulating Agents[a]

Agent	Dosage	Species/Comments
Acemannan (CarraVet, Carrington Laboratories)	—	Has been demonstrated in poultry to induce macrophages to secrete interferon, tumor necrosis factor-α, and interleukins and thus may have immunostimulant, antiviral, antineoplastic, and gastrointestinal properties; used as adjuvant in some avian vaccines
	1–2 mg/kg SC or intralesional q7d	Chemotherapeutic adjunct therapy
Acyclovir (Zovirax, Burroughs Wellcome)	—	Antiviral agent; active against herpesviruses and cytomegalovirus; IM injection of the water-soluble sodium salt (IV formulation) may cause severe muscle necrosis; phlebitis and neurologic signs may occur with IV administration; most effective when administered before clinical signs begin; birds should be treated for a minimum of 7 days; the reconstituted solution is unstable and should be divided into aliquots and frozen
	10 mg/kg IM q24h × 5–14 days	Chickens/Marek disease
	20–40 mg/kg IM q12h	Psittacines/psittacine herpesvirus
	29 mg/bird PO q8h × 7 days	Pigeons/herpesvirus
	80 mg/kg PO q8h × 7 days	Quaker parakeets/PD; psittacine herpesvirus prophylaxis or treatment
	120 mg/kg PO q12h	Tragopans/PD
	330 mg/kg PO q12h × 4–7 days	Psittacine neonates/psittacine herpesvirus
	330 mg/kg PO q12h	Raptors/falcon and owl herpesvirus; may cause vomiting
	1000 mg/L drinking water	Quaker parakeets/herpesvirus; gavage
Amantadine (Symmetrel, Endo Labs)	—	Antiviral agent; inhibits replication of influenza A viruses
	1 mg/kg PO q24h × 3 weeks	Grey parrots/no effect on avian bornavirus infection
	10 mg/kg PO × 3 days pre- and 18 days postexposure	Turkeys/influenza viruses; must be administered before and during virus exposure
	25 mg/kg PO × 10 days following infection	Chickens
	100 mg/L drinking water	Chickens/can use simultaneously with killed influenza vaccine
Entecavir (Baraclude, Bristol-Myers Squibb)	—	Oral antiviral drug used in the treatment of hepatitis viruses
	1 mg/kg PO q24h × 14 days[53]	Ducklings/PD; antiviral agent; duck hepatitis B; given with duck hepatitis B virus (DHBV) deoxyribonucleic acid vaccines
Famciclovir (Famvir, Novartis)	25 mg/kg PO q12h	Ducklings/PD; antiviral agent; duck hepatitis; toxic effects were not reported
Imiquimod cream (Aldara, 3M)	Topical application	Psittacines/cloacal papillomatosis; thought to boost host cell-mediated immunity; masses decreased in size in one report, but not in another; complete remission did not occur in either
Interferon-α2a	—	Glycoprotein with immunomodulating and antiproliferative capabilities as well as antiviral activity
	30 U q24h × 5 days, 30 U 2×/week × 2 weeks, then 30 U q7d × 2 weeks	Most species
	60–240 U/kg SC, IM q12h or 300–1200 U/kg PO q12h	Most species/stock solution: mix 1 mL (3,000,000 U/mL) with 100 mL sterile water (30,000 U/mL); can freeze as 2 mL vials up to 1 year; mix 2 mL of stock into 1 L LRS (60 U/mL); refrigerate up to 3 months
Levamisole	—	Anthelmintic with immunostimulation properties; low therapeutic index (toxic reactions and deaths reported)
	1.25–2.5 mg/kg PO, IM, SC q7–14d	Most species
Oseltamivir	—	Neuraminidase inhibitor used for treatment of avian influenza
	0.5 mg/kg PO q12h × 5 days[39]	Duck, chickens/PD; administered prophylactically to healthy animals in the event of an outbreak in valuable zoological collections
Penciclovir (Denavir, Novartis)	10 mg/kg IP q24h × 12–24 weeks	Ducks/PD; antiviral agent active against herpesviruses; DHBV; viral levels were significantly reduced; no toxic effects observed; dissolve in 2 mL of 1% DMSO
Rimantadine (Flumadine, Forest)	100 mg/L drinking water	Chickens/influenza viruses; must be used before and during exposure

[a]All antiviral drugs are banned in food-producing species in the United States as well as some other countries. Use with caution and follow local laws regarding administration to food animals.

DMSO, Dimethyl sulfoxide; *IM,* intramuscular; *IV,* intravenous; *LRS,* lactated Ringer's solution; *PO,* oral; *SC,* subcutaneous.

TABLE 4

Antiparasitic Drugs

Agent	Dosage	Species/Comments
Albendazole	5–50 mg/kg PO	Broad-spectrum anthelmintic; may be toxic in keas, some Columbiformes at 50–100 mg/kg
Amprolium	13–30 mg/kg PO	Pyrimidine derivative coccidiostat; most species
Carnidazole[a]	5–50 mg/kg PO	Treatment for *Trichomonas*, *Giardia*, *Hexamita*, *Histomonas*, most species
Chloroquine phosphate	5–25 mg/kg PO	Generally used with primaquine for *Plasmodium*, *Haemoproteus*, and *Leucocytozoon*; overdose can result in death
Clazuril	3–7 mg/kg PO	Most species: drug detected in eggs after multiple dosing
Diclazuril	5–10 mg/L drinking water	Some *Eimeria* resistance in poultry documented recently; rotate for long-term prevention
Fenbendazole	10–50 mg/kg PO	Most species/anthelmintic effective against cestodes, nematodes, trematodes, *Giardia*, and acanthocephalans; toxicity documented in pigeons and doves; may be toxic to other species, including raptors, vultures, lories, storks, and pelicans
Fipronil	7.5 mg/kg; spray on skin once, repeat in 30 days PRN	Apply via pad to base of neck, tail base, and under each wing; avoid plumage during application; alcohol may create dry, brittle feathers; do not soak bird; do not exceed 7.5 mg/kg
Flubendazole	4–20 mg/kg PO once or split over 3–9 days[145]	Gray partridge/*Trichostrongylus tenuis*
	1.43 mg/kg in drinking water for 7 days[183]	Chickens/*Ascaridia galli*; birds were found to be reinfected within 7 days
	30 ppm in feed[181]	Chickens/effective against *Ascaridia galli*, *Heterakis gallinarum*, and *Capillaria*
	1.2 g/kg of feed[77]	Geese/*Cyathostoma bronchialis*; eliminated clinical signs but these recurred, and subsequent treatment with fenbendazole was effective
Imidocarb dipropionate	5–7 mg/kg IM once, repeat in 7 days	Raptors/*Babesia*; some cases require a total of 3 treatments
Ivermectin	0.2–0.4 mg/kg PO, SC, IM, topical once, can repeat in 10–14 days	Dilute with water or saline for immediate use; dilute with propylene glycol for extended use; parenteral ivermectin may be toxic to finches and budgerigars
Levamisole	1.5 mg/kg topically split between both eyes q7d for 2 doses[129]	Ostriches/*Philophthalmus gralli*
	16 mg/kg PO q24h × 3 days[177]	Chickens/reduced fecal helminth egg burden; not as effective as fenbendazole
	25–43 mg/kg PO once[68]	Brown kiwi/highly toxic; 6/9 birds died within 4 hours
	28 mg/kg PO once[57]	Chickens/*Ascaridia galli*
	28 mg/kg in drinking water provided for 8 hours[57]	Chickens/*Ascaridia galli*
Metronidazole[a]	10–30 mg/kg PO q12	Most species/antiprotozoal, including alimentary tract protozoa (especially flagellates such as *Giardia*, *Histomonas*, *Spironucleus*, and *Trichomonas*)
	30–50 mg/kg PO q24h	Most species
	100 mg/L drinking water or soft food	Canaries
	200 mg/L drinking water × 7 days	Passerines
Milbemycin oxime	2 mg/kg PO, repeat in 28 days	Galliformes
Paromomycin	—	Aminoglycoside with antiprotozoal activity
	50–100 mg/kg PO q8–24h[189]	Falcons/*Cryptosporidium baileyi*; no apparent efficacy
	100–400 ppm in feed[89]	Turkeys/*Histomonas meleagridis*; flock mortality only 20% at 400 ppm
	5 mg/kg in feed for 6 weeks[112]	Turkeys/*Histomonas meleagridis*; 2 out of 3 flocks required early culling due to high mortality rates
Ponazuril	10–20 mg/kg PO repeat in 10–14 days	Most species including pigeons, waterfowl
	25 mg/kg PO, IM, repeat in 10–14 days	Bali mynahs/cestodes

Continued

TABLE 4

Antiparasitic Drugs—cont'd

Agent	Dosage	Species/Comments
Praziquantel	—	Anthelminthic
	10 mg/kg PO q7d × 4 weeks[35]	Passerines/*Szidatitrema* trematodes; effective in most birds; those that remained positive on fecal examination after several months were then treated with 20 mg/kg IM q7d × 4 weeks
	10–100 mg/kg IM q14d[3]	Chickens/not effective against *Philophthalmus gralli*
	20 mg/kg PO once[154]	Black stilts/no difference in fecal egg counts between treated and control groups
	40–200 mg/kg IM once[14]	Common mergansers/schistosomes; 40 mg/kg was insufficient whereas 200 mg/kg reduced parasite load
	56.8–85.2 mg nebulized in 100% oxygen[35]	Blue-crowned motmots (n = 2) and fairy bluebird (n = 1)/effective at reducing total parasite burden of air sac trematodes
	Topically OU q12h (1% ointment)[25]	Greater rheas/*Philophthalmus gralli*
Primaquine	—	Hematozoa (i.e., *Plasmodium*, *Haemoproteus*, and *Leucocytozoon*); use in conjunction with chloroquine; dosage based on amount of active base rather than total tablet weight
	0.3 mg/kg PO (at 24 hours following the initial chloroquine dose) q24h × 7–10 days	Penguins and raptors/use with chloroquine (10 mg/kg at 0 hours, then 5 mg/kg at 6, 24, and 48 hours)
	0.75–1 mg/kg PO once	Most species, including raptors/*Plasmodium*; use with chloroquine (25 mg/kg at 0 hours, then 15 mg/kg at 12, 24, and 48 hours); palliative therapy
	1 mg/kg PO q7d	Use with chloroquine (10 mg/kg q7d) as a preventative regimen for birds recovering from *Plasmodium* infection
	1 mg/kg PO q24h × 2 days, repeat q7d × 3–5 treatments to prevent relapse	Raptors/*Plasmodium*; use with chloroquine (20 mg/kg IV initially, followed by 10 mg/kg PO at 6, 18, and 24 hours)
	15 mg PO[20]	African penguins/PK
Pyrimethamine (Fansidar, Roche)	—	Most species/*Atoxoplasma*, *Plasmodium*; chloroquine and primaquine are preferred; overdosage may cause hepatotoxicity; *Toxoplasma*, *Atoxoplasma*, *Sarcocystis*; may be effective for *Leucocytozoon*; supplement with folic acid
	0.25–0.5 mg/kg PO q12h × 30 days	Raptors, waterfowl/*Sarcocystis*, *Toxoplasma*
	0.5 mg/kg PO q12h × 14–28 days	Most species/use for 28 days for *Leucocytozoon* in raptors
	0.5 mg/kg PO q12h × 30 days	Waterfowl/*Sarcocystis*
	0.5–1 mg/kg PO q12h × 30 days	Eclectus, Amazon parrots/use with trimethoprim-sulfadiazine (30 mg/kg)
	1 mg/kg feed	Game birds
	100 mg/kg feed	Most species
Quinacrine HCl (Atabrine, Sanofi)	—	Most species/*Atoxoplasma*, *Plasmodium*; chloroquine and primaquine preferred; overdosage may cause hepatotoxicity
	5–10 mg/kg PO q24h × 7–10 days	Most species/use higher doses for *Atoxoplasma*, *Lankesterella*, *Plasmodium*
	26–79 mg/L drinking water × 10–21 days	Pigeons
Ronidazole[a]	2.5 mg/kg PO × 6 days	Pigeons
	6–10 mg/kg PO q24h × 6–10 days	Most species
	10–20 mg/kg PO q24h × 7 days	Pigeons
Selamectin	—	No adverse effects, including neurological signs, were seen in healthy zebra finches with doses up to 92 mg/kg
	20 mg/kg topically q19d[90]	Helmeted guineafowl/PK
	20 mg/kg topically q14d[152]	Lorikeets (*Trichoglossus* spp.)/PK
	23 mg/kg topically, repeat in 3–4 weeks	Budgerigars/*Knemidocoptes* improvement 13/14 birds at 4 weeks, no neurological signs identified but monitor for weight loss

TABLE 4

Antiparasitic Drugs—cont'd

Agent	Dosage	Species/Comments
Sulfachloropyrazine	1 g of 30% powder/L of drinking water × 5 days, off 3 days, on 5 days, then repeat cycle 4×; administer treatment 3× annually	Bali mynahs/*Atoxoplasma*; significantly reduced or totally cleared oocyst shedding for extended time; it is uncertain if the drug is safe to use when parents are feeding chicks; supplement with vitamin B_6. No adverse effects, including neurological signs, were seen in healthy zebra finches with doses up to 92 mg/kg
Sulfachloropyridazine	150–300 mg/L drinking water; 5 days/week × 2–3 weeks	Passerines, including canaries/may need to treat for months for systemic coccidiosis
	300 mg/L drinking water × 5 days, off 3 days, on 5 days, then repeat cycle 4×; administer treatment 3× annually	Passerines, including Bali mynahs/*Atoxoplasma*
	300 mg/L drinking water × 7–10 days	Pigeons
	300–1000 mg/L drinking water × 3 days, off 2 days, then repeat course	Pigeons
	400–500 mg/L drinking water × 5 days, off 2 days, on 5 days	Most species
Sulfadimethoxine	25 mg/kg PO q12h × 5 days	Raptors
	25–50 mg/kg PO q24h × 3 days	Raptors
	25–50 mg/kg PO q24h × 3 days, off 2 days, then q24h × 3 days	Raptors/*Eimeria*, *Sarcocystis*
	25–55 mg/kg PO q24h × 3–7 days	Raptors
	50 mg/kg PO once, followed by 25 mg/kg PO q24h × 7–10 days	Psittacines
	50 mg/kg PO q24h × 5 days, off 3 days, on 5 days	Pigeons/close to toxic levels
	250 mg/L drinking water × 5 days	Turkeys
	330–400 mg/L drinking water × 1 day then 200 mg/L × 4 days	Pigeons/supplement with vitamin B for 5 days
	500 mg/L drinking water × 6 days	Chickens
Sulfaquinoxaline	—	Contraindicated with dehydration, liver disease, or bone marrow suppression; gastrointestinal upset, regurgitation are common, especially in macaws; use for longer than 2 weeks may require vitamin B (folic acid) supplementation
	250 mg/L drinking water × 6 days, off 2 days, on 6 days	Turkeys
	400 mg/L (1.4 mL/L) drinking water × 6 days, off 2 days, on 6 days	Chickens
	500 mg/L (1.8 mL/L) drinking water × 6 days, off 2 days, on 6 days	Pigeons
	225 mg/kg feed continuously	Turkeys
	450 mg/kg feed continuously	Chickens
Thiabendazole	40–100 mg/kg PO q24h × 7 days	Most species
	50 mg/kg PO, repeat in 14 days	Ostriches
	100 mg/kg PO once, repeat in 10–14 days	Raptors
	100–200 mg/kg PO q12h × 10 days	Raptors/nematodes; may interfere with egg laying
	100–500 mg/kg PO once	Most species
	250–500 mg/kg PO, repeat in 10–14 days	Most species, including psittacines
	425 mg/kg feed × 14 days	Pheasants, cranes

Continued

TABLE 4

Antiparasitic Drugs—cont'd

Agent	Dosage	Species/Comments
Toltrazuril (Baycox, Bayer)	—	Has been successful in reducing mortality from *Atoxoplasma* in passerines and may affect systemic stages of the disease; not very effective against *Atoxoplasma* when given in water; bitter taste, mixing with soft drink (e.g., cola) increases palatability; 2.5% solution is very alkaline and should not be gavaged directly into the crop
	7 mg/kg PO q24h × 2–3 days	Budgerigars, raptors
	10 mg/kg PO q24h × 2 days	Raptors/preferred treatment for *Caryospora*
	10 mg/kg PO q48h × 3 treatments	Raptors/treatment of choice for coccidiosis in falcons
	12.5 mg/kg PO q24h × 14 days	Bali mynahs/*Atoxoplasma*; dosage is based on a limited number of clinical cases
	15–25 mg/kg PO q24h × 2 days	Raptors
	25 mg/kg PO q7d × 3 treatments	Raptors
	50 mg/kg PO once	Most species/*Giardia*, *Trichomonas*, *Entamoeba*
	2 mg/L drinking water × 2 consecutive days/week	Psittacines
	5 mg/L drinking water × 2 days, repeat in 14–21 days	Lories/10 mg/L administered during second course of treatment
	12.5 mg/L drinking water × 2 days	Waterfowl
	20 mg/kg in drinking water × 2 days	Pigeons
	25 mg/L drinking water × 2 days	Chickens
	25 mg/L drinking water × 2 days, repeat in 14–21 days	Cockatiels, passerines (including goldfinches, manikins, siskins)
	75 mg/L drinking water × 2 days/week × 4 weeks	Passerines
	125 mg/L drinking water × 5 days	Pigeons
	200–400 mg/kg feed	Chickens/*Histomonas*; depressed weight gain on higher dosage
Trimethoprim-sulfadiazine	5 mg/kg IM q12h	Companion birds/*Sarcocystis*; use in conjunction with pyrimethamine (0.5–1 mg/kg PO q12h × 2 days, then 0.25 mg/kg PO q12h × 30 days)
	30 mg/kg PO q8–12h	Most species, including psittacines, raptors/*Sarcocystis* (treat for at least 6 weeks); coccidia
	60 mg/kg PO, SC q12h × 3 days, off 2 days, on 3 days	Raptors, waterfowl/coccidia
	80 mg/mL drinking water (trimethoprim)/40 mg/mL water (sulfadiazine)	Canaries/*Toxoplasma gondii*
Trimethoprim-sulfamethoxazole	25 mg/kg PO q24h	Toucans, mynahs/coccidia
	30 mg/kg PO q12–24h	Passerines/antiprotozoal
	320–525 mg/L drinking water	Poultry/coccidia
	480 mg/L drinking water q24h	Pigeons/antiprotozoal; see sulfonamides

[a]These drugs are banned in food-producing species in the United States as well as some other countries. Use with caution and follow local laws regarding administration to food animals.

IM, Intramuscular; *IV,* intravenous; *OU,* both eyes, *PK,* pharmacokinetic; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 5

Chemical Restraint/Anesthetic/Analgesic Agents[a]

Agent	Dosage	Species/Comments
Acepromazine	0.1–0.2 mg/kg IV 0.25–0.5 mg/kg IM	Ratites/most commonly used in combination with other anesthetics; rarely used in other species
Alfaxalone (Alfaxan, Jurox Pty Ltd)	—	Neuroactive steroid, $GABA_A$ receptor antagonist
	2 mg/kg IV[190]	Greater flamingos/smoother and shorter induction than with isoflurane
	4–7.5 mg/kg IV[121]	Chickens/induction of general anesthesia; lower doses required with premedication
	10 mg/kg IM or IV[108]	Mallard ducks/insufficient anesthesia for invasive procedures
	10 mg/kg IM[48]	Budgerigars/effective sedation, adequate for short minimally invasive procedures
	10–25 mg/kg IM[196]	Quaker parrots/induction agent; longer induction with lower dose; longer recovery at higher dose; addition of midazolam 1 mg/kg to protocol decreased muscle tremors and hyperexcitation
	10–50 mg/kg SC[138]	Bengalese finches/anesthetic induction agent; reduced induction time and longer duration with higher doses; faster induction and longer duration with addition of midazolam 0.7 mg/kg SC; longer duration with butorphanol 1 mg/kg SC
	15–20 mg/kg IM[10,156]	Budgerigars/mild-to-moderate sedation at 15 mg/kg; moderate-to-profound sedation at 20 mg/kg; duration about 30 minutes at either dose; both doses caused a significant decrease in respiratory rate
Amantadine (Symmetrel, Endo Labs)	—	Increases CNS dopamine release; weak NMDA receptor antagonist; synergistic with NSAIDs, opioids, gabapentin
	5 mg/kg PO q24h[13]	Orange-winged Amazons/PK
Atipamezole	2.5×–5× alpha-2 adrenergic agonist dose IM, IV	Alpha-2 adrenergic antagonist; 1:1 volume reversal of dexmedetomidine and medetomidine is general rule; can be divided ½ IM and ½ SC
Atropine sulfate	0.01–0.02 mg/kg SC, IM, IV	Most species/premedication
	0.04–0.1 mg/kg SC, IM, IV, IO, IT	Most species/bradycardia; higher doses with CPR
Bupivacaine HCl	—	May be shorter acting in some birds; minimize dose to limit potential toxic effects
	2 mg/kg infused SC	Mallard ducks/PD; high plasma levels at 6 and 12 hours postadministration so possible for delayed toxicity
	2–8 mg/kg perineurally	Mallard ducks/variable effectiveness for brachial plexus nerve block
Buprenorphine	0.6–1.8 mg/kg IM[85]	Cockatiels/did not change thermal nociceptive threshold
	0.6 mg/kg IM, IV q6–9h[78]	American kestrels/PK
	1.8 mg/kg SC q24h[72]	Red-tailed hawks/PK
Buprenorphine SR-LAB sustained-release formulation (Wildlife Pharmaceuticals)	1.8 mg/kg SC, IM q12–72h[80,87]	American kestrels/PK
Butorphanol tartrate	—	PO bioavailability <10% in Hispaniolan Amazon parrots; do not recommend in American kestrels
	0.05–0.25 mg/kg IV	Ratites
	0.5–5 mg/kg IM, IV q1–4h	Most species, including psittacines
	2–4 mg/kg IV[50]	Guineafowl; reduced sevoflurane MAC
	3 mg/kg (premedication) + 75 μg/kg/minute IV CRI (maintenance)	Psittacines; significantly reduced isoflurane MAC
	247 μg/kg/hour via osmotic pump implanted SC[26]	Peafowl/PK
Butorphanol tartrate in poloxamer 407 gel	12.5 mg/kg SC q4–8h[109]	Hispaniolan Amazon parrots/PK; long-acting formulation has longer half-life
Dexmedetomidine HCl	25 μg/kg IM	Common buzzards/adequate restraint to prevent reaction to handling but did not allow for intubation; no arrhythmias, excitement, or major adverse effects noted; complete reversal with atipamezole
	75 μg/kg	Common kestrels/adequate restraint to prevent reaction to handling but did not allow for intubation

Continued

TABLE 5

Chemical Restraint/Anesthetic/Analgesic Agents—cont'd

Agent	Dosage	Species/Comments
Diazepam	0.05–0.5 mg/kg IV	Most species
	0.25–0.5 mg/kg IM, IV q24h × 2–3 days	Raptors/appetite stimulant
	5 mg/kg PO, IV	Ratites/sedation
	5–10 mg/kg IM[144]	Zebra finches/deep sedation for several hours; complete recovery with flumazenil
	12–15 mg/kg intranasally	Ring-necked parakeets, canaries/dose divided into each naris and given slowly; intranasal flumazenil significantly reduced recumbency time
Dobutamine	15 μg/kg/minute IV[167]	Beta-1 adrenergic agonist used to treat anesthetic-induced hypotension
Dopamine HCl	7–10 μg/kg/minute IV[167]	Inotropic vasopressor used to treat anesthetic-induced hypotension
Fentanyl citrate	0.2 mg/kg loading dose + 10–30 μg/kg/minute IV CRI	Reduced isoflurane MAC 31%–55% in a dose-related manner in red-tailed hawks; significant effects on heart rate/blood pressure in Hispaniolan Amazon parrots
	20 μg/kg IV[92]	Hispaniolan Amazon parrots/PK; significantly decreased MAC of isoflurane but caused decreased heart rate and blood pressure
Transdermal fentanyl solution (Recuvyra, Elanco)	5 mg/kg topically q7d[194]	Guineafowl/PK
Fentanyl transdermal patch (Duragesic, Janssen Pharmaceuticals)	25 μg/hour for 72 hours[34]	Chickens/PK
Flumazenil	0.02–0.05 mg/kg IM, IV	Most species
	0.05–0.25 mg/kg intranasally incorrect citation	Canaries, Hispaniolan Amazon parrots, ring-necked parakeets/dose divided evenly between nares and given slowly, significantly reduced recumbency time
Gabapentin	—	Neuropathic pain (chronic pain; often associated with traumatic and self-induced injuries); analgesic
	10 mg/kg PO q12h	Little corella/long-term analgesia (>90 days); sole analgesic for self-mutilation; no adverse effects noted
	11 mg/kg PO q12h	Prairie falcon/long-term (>90 days) analgesic adjunct to multimodal therapy for self-mutilation
	11 mg/kg PO q8h[203]	Great horned owls/PK
	15 mg/kg PO q8h[8]	Hispaniolan Amazon parrots/PK
	25 mg/kg PO q12h[18]	Caribbean flamingos/PK
	30 mg/kg PO[7]	Hispaniolan Amazon parrots/PD; additional studies are needed
Glycopyrrolate	0.01–0.02 mg/kg IM, IV	Most species/preanesthetic
Hydromorphone HCl	0.1–0.6 mg/kg IM[98]	Cockatiels/did not increase thermal withdrawal threshold despite plasma concentrations considered therapeutic for other species
	0.1–0.6 mg/kg IM[83]	American kestrels/increased thermal withdrawal threshold for up to 6 hours; appreciable sedation in several birds at 0.6 mg/kg dose
	0.6 mg/kg IM q6h[88]	American kestrels/PK
	1 mg/kg IM, IV q6h[86]	Orange-winged Amazon parrots/PK
	1–2 mg/kg IM q3–6h[82]	Orange-winged Amazon parrots/significantly increased thermal withdrawal threshold but caused agitation, ataxia, and signs of nausea
Ketamine HCl	—	Seldom used as sole agent because of poor muscle relaxation and prolonged, violent recoveries; may produce excitation or convulsions; may fail to produce general anesthesia in some species including raptors and waterfowl
	5–50 mg/kg SC, IM, IV	Smaller species require a higher dose; large birds tend to recover more slowly
	50 mg/kg IO	Pigeons/provided effective anesthesia

TABLE 5

Chemical Restraint/Anesthetic/Analgesic Agents—cont'd

Agent	Dosage	Species/Comments
Ketamine (K)/diazepam (D)	(K) 2–5 mg/kg IV + (D) 0.25 mg/kg IV	Ostriches/ketamine may be given 15–30 minutes after diazepam
	(K) 3–8 mg/kg + (D) 0.5–1 mg/kg IM	Eagles, vultures
	(K) 8–15 mg/kg + (D) 0.5–1 mg/kg IM	Falcons
	(K) 10–40 mg/kg IV + (D) 1–1.5 mg/kg IM, IV	Raptors, pigeons, waterfowl/rapid bolus may produce apnea, arrhythmia, and increased risk of death
	(K) 20 mg/kg + (D) 1 mg/kg IV	Toucans/short procedures (15–20 minutes)
	(K) 75 mg/kg IM + (D) 2.5 mg/kg IV	White leghorn cockerels/ diazepam administered 5 minutes before ketamine for typhlectomy; some limb contracture, hypothermia, hypoxia, hypercapnia
Ketamine (K)/midazolam (Mi)	(K) 10–40 mg/kg + (Mi) 0.2–2 mg/kg SC, IM	Most species, including psittacines
	(K) 40–50 mg/kg + (Mi) 3.65 mg/kg intranasally	Ring-necked parakeets/dose divided into each nare and given slowly; onset of action less than 3 minutes, dorsal recumbency for 70.7 ± 46.7 minutes, recovery times reduced with flumazenil intranasally
Ketamine (K)/midazolam (Mi)/butorphanol (B)	(Mi) 0.2 mg/kg + (B) 0.4 mg/kg IM followed by (K) 8.7 ± 0.5 mg/kg IV	Ostriches/induction; followed by intubation and isoflurane anesthesia
Lidocaine	—	Toxic effects have been documented in birds at overall lower total doses (2.7–3.3 mg/kg) than dogs; may need to dilute 1:10 in small birds
	1–3 mg/kg	Most species
	15 mg/kg + 3.8 μg/kg lidocaine perineurally	Mallard ducks/variable effectiveness for brachial plexus nerve block
Midazolam HCl	0.1–2 mg/kg IM, IV	Most species/premedication at lower doses, onset approximately 15 minutes when administered IM
	0.15 mg/kg IV	Ostriches/rapid sternal recumbency in adults
	1 mg/kg IM[120]	Budgerigars/increased food intake for 1 hour following administration
	2 mg/kg intranasally[118]	Hispaniolan Amazon parrots/mild-to-moderate sedation in 3 minutes; reduced vocalizations, struggling, and defensive behaviors for 15 minutes; reversed with intranasal flumazenil
	3 mg/kg intranasally[41]	Cockatiels/median onset of sedation 85 seconds
	3 mg/kg + butorphanol 3 mg/kg intranasally[41]	Cockatiels/improved sedation compared to midazolam alone
	2–6 mg/kg IM	Quail/PD; mild-to-heavy sedation
	5 mg/kg IV	Turkeys, chickens, ring-necked pheasants, bobwhite quail
	7.3–8.8 mg/kg intranasally[211]	Ring-necked parakeets, canaries/dose divided into each nare and given slowly; time to onset, 3 minutes; dorsal recumbency, 57.7 ± 24.4 minutes; flumazenil administered intranasally significantly reduced recovery time
	12.5–15.6 mg/kg intranasally[210]	Canaries/dose divided into each nare and given slowly; time to onset, less than 3 minutes; dorsal recumbency, 17.1 ± 5 minutes; flumazenil intranasally significantly reduced recovery time
Nalbuphine HCl	12.5 mg/kg IM q2–3h	Opioid partial κ-agonist and partial μ-antagonist; Hispaniolan Amazon parrots/PK, PD; excellent bioavailability, little sedation; rapidly cleared after IM dosing; higher dosages (25 and 50 mg/kg IM) did not significantly increase withdrawal values
Naloxone HCl	0.01 mg/kg IV	Ostriches
	2 mg IV q4–12h	Most species, including psittacines
Naltrexone HCl	300–330 mg IM, IV	Ostriches

Continued

TABLE 5

Chemical Restraint/Anesthetic/Analgesic Agents—cont'd

Agent	Dosage	Species/Comments
Propofol	—	IV sedative-hypnotic agent; give slowly for induction to minimize apnea; intubation and IPPV required
	1–5 mg/kg IV	Most species/induction
	3 mg/kg IV (induction); 0.2 mg/kg/minute IV (maintenance)	Ostriches/PD; anesthesia
	4 mg/kg IV (induction); 0.5 mg/kg/minute IV (maintenance)	Barn owl/anesthesia
	5 mg/kg IV (induction); 1 mg/kg/minute IV (maintenance)	Hispaniolan Amazon parrots/PD; recovery times (15.4 ± 15.2 minutes) were prolonged when compared with isoflurane; 6 of 10 birds had agitated recoveries; light anesthetic plane in 8 of 10 birds
Tapentadol	—	μ-Opioid receptor agonist, norepinephrine reuptake inhibitor similar to tramadol
	30 mg/kg PO[42]	Hispaniolan Amazons/PK; only 2/7 birds had detectable plasma levels
Tolazoline HCl	1 mg/kg IV	Ostriches
	15 mg/kg IV	Raptors, including vultures
Tramadol HCl	5 mg/kg PO, IV q12h	Bald eagles/similar plasma concentrations to humans for analgesia (but analgesia not evaluated); PO bioavailability in bald eagles higher than in humans and dogs; monitor for sedation and reduce dose and/or frequency PRN
	5–30 mg/kg PO[84]	American kestrels/PD; 5 mg/kg dose resulted in longest duration of action (3 hours)
	7.5 mg/kg PO	Peafowl/2 of 6 birds reached human tramadol analgesic concentrations
	8–11 mg/kg PO q12h	Red-tailed hawks/15 mg/kg PO q12h data model suggested more frequent dosing to achieve human analgesic plasma tramadol concentrations; monitor for sedation and reduce dose and/or frequency PRN
	10 mg/kg IM[49]	White-eyed parakeets/did not change MAC of isoflurane
	10 mg/kg PO q24h[104]	African penguins/PK
	30 mg/kg PO q6–8h[179,180]	Hispaniolan Amazon parrots/similar plasma concentrations to humans for analgesia
	30 mg/kg PO q12h[5]	Muscovy ducks/PK

[a]All opioid agonists and agonist-antagonists may cause respiratory depression; profound bradypnea may occur with potent opioid agonists. *CNS,* Central nervous system; *CPR,* cardiopulmonary resuscitation; *CRI,* constant rate infusion; *$GABA_A$ receptor,* gamma-amino butyric acid A receptor; *IM,* intramuscular; *IO,* intraosseous; *IPPV,* intermittent positive pressure ventilation; *IT,* intratracheal; *IV,* intravenous; *MAC,* minimum alveolar concentration; NMDA, *N*-methyl-D-aspartate; *NSAID,* nonsteroidal antiinflammatory drug; *PD,* polydipsia; *PK,* pharmacokinetic; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 6

Nonsteroidal Antiinflammatory Agents[a,b]

Agent	Dosage	Species/Comments
Carprofen	2–10 mg/kg SC, IM	Most species; caution should be used when administering to *Gyps* vultures; Hispaniolan Amazon parrots may need more frequent dosing recommended than q12h
	11.5 mg/kg PO[63]	Cape vultures/mild depression and lethargy noted after single dose, as well as transient (≤48 hours) increase in blood uric acid
	30 mg/kg IM	Chickens/PD; arthritis painful behaviors reduced 1 hour posttreatment only with this high dose
Celecoxib (Celebrex, Pfizer)	10–80 mg/kg PO q24h × 6–24 weeks	Psittacines/clinical proventricular dilatation disease; clinical improvement may be seen within 14 days. Higher doses of up to 80 mg/kg have been anecdotally used for neurological cases
Diclofenac		Highly toxic to *Gyps* vultures
	2.5 mg/kg IM q24h × 5 days	Chickens/3/6 birds died; significant increases in serum uric acid, ALT, AST, creatinine; extensive visceral gout on necropsy
Flunixin meglumine	1 mg/kg PO[63]	Cape vultures/mild depression and lethargy noted after single dose, as well as transient (≤48 hours) increase in blood uric acid
	5 mg/kg IV[130]	Budgerigars, Patagonian conures/PK; half-life less than 1 hour but plasma levels above the level considered antiinflammatory and analgesic
Grapiprant	30 mg/kg PO	Red-tailed hawks/PK; plasma concentrations of approximately 100 times the canine therapeutic concentrations were achieved. Toxicity at current unknown though regurgitation was seen at doses of 45 mg/kg
Ibuprofen	5–10 mg/kg PO q8–12h	Psittacines/use pediatric suspension for small birds; avoid in *Gyps* vultures
Ketoprofen	1–5 mg/kg IM q12h	Avoid in *Gyps* vultures; raptors, waterfowl
	2.5 mg/kg IM q24h × 3 or 7 days	Budgerigars/low frequency of glomerular congestion, degeneration/dilation of tubules occurred at 3–7 days treatment
	3 mg/kg IM q24h × 5 days[124]	Broiler chickens/no adverse effects noted
	5–10 mg/kg IM, IV	Waterfowl; caution in eider ducks/high mortality may be owing to high bupivacaine dose, or cumulative toxicity of bupivacaine and ketoprofen
Mavacoxib	4 mg/kg PO	Cockatiels/PK; elimination half-life of 135 hours
	6 mg/kg PO	Flamingos/PK; plasma concentrations maintained >0.4 µg/mL for 120 hours
Meloxicam	—	No reported mortalities including *Gyps* vultures, few studies evaluating renal effects of higher doses
	0.2 mg/kg PO[96]	Brown pelicans/PK; elimination half-life 36 hours
	0.5 mg/kg PO[209]	Lesser flamingos/PK; insufficient plasma levels achieved
	0.5 mg/kg IM q24h[128]	African penguins/PK
	0.95 mg/kg PO q24h[23]	Emus/PK
	1 mg/kg PO q48h[128]	African penguins/PK
	1 mg/kg PO q12h × 5 days[178]	Chickens/PK; achieved plasma levels associated with analgesia in humans; recommended egg withdrawal time is 2 weeks after last dose
	1 mg/kg PO, IM[16]	American flamingos/PK; insufficient plasma levels with oral administration; short half-life (1.83 hours) with IM administration
	1 mg/kg PO q24h[127]	Grey parrots/PK; plasma levels maintained above those considered effective for analgesia in other avian species
	1 mg/kg PO, IM, IV q12h[125]	Hispaniolan Amazon parrots/improved weight-bearing on arthritic limb compared with lower doses; PO lower bioavailability than parenteral; concentrations similar to humans for analgesia for IM, IV for only 6 hours
	1–2 mg/kg IM q24h × 4 days[123]	Zebra finches/PK
	2 mg/kg IM q12h × 14 days	Japanese quail/unremarkable histological and minimal biochemical changes
	2 mg/kg IM, PO	Cape griffon vultures/rapid metabolism and short elimination t½ suggests low potential for drug accumulation
	3 mg/kg SC sustained-release formulation[81]	Hispaniolan Amazon parrots/PK; highly variable half-life; not currently recommended
	3 mg/kg SC sustained-release formulation[173]	American flamingos/PK; parameters no different than standard formulation
	5 mg/kg PO BID × 5 days[97]	Chickens; 3/11 birds died during treatment course; 7/11 had gross and histologic evidence of gout; not recommended
	1.5–5 mg/kg transdermally (in pluronic lecithin organogel suspension)[19]	Red-tailed hawks/PK; no plasma levels detected at 1.5 or 3 mg/kg; plasma levels after 5 mg/kg much lower than previously established therapeutic levels

Continued

TABLE 6

Nonsteroidal Antiinflammatory Agents—cont'd

Agent	Dosage	Species/Comments
Phenylbutazone	1.7 mg/kg PO[63]	Cape vultures/mild depression and lethargy noted after single dose, as well as transient (≤48 hours) increase in blood uric acid
Piroxicam	—	Has been used to treat pain associated with chronic degenerative joint disease in cranes and other species
	0.5 mg/kg q12h	Psittacines
	0.5–1 mg/kg PO[102]	Brolgas/PK; insufficient sampling duration to determine half-life
	0.5–0.8 mg/kg PO q12h[c]	Whooping cranes/used for acute myopathy, chronic degenerative joint disease
Robenacoxib (Onsior, Elanco)	2–10 mg/kg IM q5–7d[d]	Psittacines/avian ganglioneuritis and proventricular dilatation disease

[a]Unless otherwise noted, drugs provide analgesic, antipyretic, and antiinflammatory effects.
[b]Nonsteroidal antiinflammatory agents may potentially cause gastrointestinal upset and hemorrhage as well as adverse renal effects ranging from fluid retention to renal failure.
[c]J. Paul-Murphy, personal communication, 2011.
[d]B.L.S. Speer, personal communication, 2022.
ALT, Alanine aminotransferase, *t½,* half life, half time, *AST,* aspartate aminotransferase; *IM,* intramuscular; *IV,* intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PO,* oral; *SC,* subcutaneous.

TABLE 7

Hormones and Steroids

Agent	Dosage	Species/Comments
Adrenocorticotropic hormone (ACTH)	1–2 U/kg IM	Psittacines/ACTH stimulation test
Arginine vasopressin	25 µg/kg IM q12h	Grey parrot/central diabetes insipidus
Arginine vasotocin	0.5–4 µg/kg IN q12h	Grey parrot/central diabetes insipidus
Calcitonin	4 U/kg IM q12h	Most species/reduce hypercalcemia (e.g., that caused by cholecalciferol rodenticide toxicity)
Human chorionic gonadotropin	500–1000 U/kg IM on days 1, 3, 7—q3–6wk PRN	Inhibits egg laying; administer on days 3 and 7 if hen lays eggs after day 1
Deslorelin acetate	—	Synthetic long-acting GnRH agonist; used to treat reproductive tract disorders or conditions exacerbated by circulating concentrations of reproductive hormones; reported to suppress ovarian carcinoma in a cockatiel[132]
	4.7-mg long-acting implant IM[17,30]	Pigeons/effective for controlling egg laying in females for at least 49 days
	4.7-mg implant SC[182]	Cockatiels/suppressed egg laying for at least 180 days
	4.7- or 9.4-mg implant placed SC intrascapularly[30,119,141]	GnRH agonist available as long-term implant; no adverse reports with use to date
	9.4-mg implant SC[140]	Japanese quail/slower onset of action and inconsistent effects compared to two 4.7 mg implants
Desmopressin	4.6 µg/kg IM q12h	Grey parrot/treatment of central diabetes insipidus
Dexamethasone[a]	0.2–1 mg/kg IM, IV once or q12–24h × 2–7 days, then q48h × 5 days	Most species, including raptors/antiinflammatory
	2–4 mg/kg IM, IV q12–24h	Most species, including ratites/shock, trauma
Dexamethasone sodium phosphate[a]	2–4 mg/kg SC, IM, IV q6h–24h	Most species/head trauma, shock, hyperthermia; higher dose for shock, head trauma, endotoxemia
Glipizide	—	Sulfonylurea antidiabetic; contraindicated in ketotic patients; patients should be maintained at trace glycosuria to prevent hypoglycemia
	0.5 mg/kg PO q12h	Cockatiels/diabetes mellitus
	1.25 mg/kg PO q24h	Most species/diabetes mellitus
Insulin	0.002 U/bird IM q12–48h	Budgerigars/NPH insulin
	0.01–0.1 U/bird IM q12–48h	Amazon parrots/NPH insulin
	0.5–3 U/kg IM	Psittacines/NPH insulin
	1.4 U/kg IM q12–24h	Cockatiels, toco toucans/NPH insulin
	2 U/bird IM	Toco toucans/ultralente or PZI; adjust dose or frequency based on glucose curves
Leuprolide acetate	—	Administration before onset of egg laying may be more successful than treatment during breeding; 1 month depot formulation generally requires q4wk treatment
	(Number of days for desired effect) × (52 or 156 µg/kg) = dosage IM	Cockatiels
	200–1000 µg/kg IM q2–6wk	Most species
	1250 µg/kg IM once	Penguins/induced molt in 1 of 2 birds dosed
Levothyroxine (L-thyroxine)	1–200 µg/kg PO q12h × 4 weeks	Psittacines, raptors
Methylprednisolone acetate[a]	200 mg/bird IM	Ratites (adults)

Continued

TABLE 7

Hormones and Steroids—cont'd

Agent	Dosage	Species/Comments
Oxytocin	0.5–10 U/kg IM	Most species; should be preceded by calcium administration for egg binding; contraindicated unless uterovaginal sphincter is well dilated and uterus is free of adhesions; used alone to stop uterine bleeding; may need to repeat injection
Prednisolone[a]	0.5–1 mg/kg IM, IV once	Most species
	1 mg/kg PO q24h[91]	Green-wing macaw/chronic lymphocytic leukemia
	1–1.25 mg/kg PO q48h	Ratites
	2 mg/kg PO q12h	Psittacines/inflammation
	2–4 mg/kg IM, IV	Raptors/shock
Prednisolone sodium succinate[a]	0.5–1 mg/kg IM, IV	Psittacines/antiinflammatory
	1.5–2 mg/kg IM q12h	Ratites/immunosuppression
	2–4 mg/kg IM, IV once	Psittacines/shock; trauma; endotoxemia; immunosuppression
	5–8.5 mg/kg IV q1h	Ratites/shock
Prednisone[a]	—	See prednisolone
Prostaglandin E2	0.02–0.1 mg/kg applied topically to the uterovaginal sphincter	Relaxes uterovaginal sphincter; lower dosage may be effective; freeze into aliquots
Prostaglandin F2α	0.02–0.1 mg/kg IM, intracloacal once	Dystocia: may be helpful when the egg is located distally and the uterovaginal sphincter is dilated; can result in uterine rupture, bronchoconstriction, hypertension, and death
Thyroid-stimulating hormone (TSH)	0.1 U IM	Cockatiels
	0.2 U/kg IM	Macaws/PD; T_4 doubled in 6 of 11 birds 4 hours after receiving TSH
	1 U/kg IM	T_4 doubled in Hispaniolan and blue-fronted Amazon parrots 6 hours after receiving TSH
	1–2 U/kg IM	Psittacines/obtain blood at 0 hours, then 4–6 hours after TSH stimulation
Trilostane	1 mg/kg q24h	Senegal parrot/Cushing disease

[a]Steroid administration may predispose birds to aspergillosis and other mycoses; administration may also be associated with the development of polyuria/polydipsia/polyphagia, increased protein catabolism, glycosuria, and diabetes mellitus; toxic levels may be attained even with topical application; administration should ideally not exceed 5 days; rapid onset, shorter-acting drugs are generally less likely to cause serious adverse effects.

GnRH, Gonadotropin-releasing hormone; *IN,* intranasal, *IM,* intramuscular; *IV,* intravenous; *NPH,* neutral protamine Hagedorn; *PD,* Pharmacodynamic; *PO,* oral; *PRN,* as needed; *PZI,* protamine zinc insulin; *SC,* subcutaneous. T_4, thyroxine

TABLE 8

Nebulization Agents[a]

Agent	Dosage	Species/Comments
N-acetyl-L-cysteine 10%–20% (Mucomyst, Bristol)	22 mg/mL sterile water until dissipated	Most species/mucolytic agent; tracheal irritation and reflex bronchoconstriction reported in mammals; use is preceded by bronchodilators in mammals; see amikacin, gentamicin, terbinafine for combinations
Amikacin	5–6 mg/mL sterile water or saline × 15 minutes q8–12h	Most species/discontinue if polyuria develops
	6 mg/mL sterile water and 1 mL acetylcysteine (20%) until dissipated q8h	Most species
Aminophylline	3 mg/mL sterile water or saline × 15 minutes	Most species/bronchial and pulmonary vasculature smooth muscle relaxation; incompatible with amikacin, cephalothin, clindamycin, erythromycin, oxytetracycline, methylprednisone, penicillin G, tetracycline; consult with specialized references for more information
Amphotericin B (Fungizone, Squibb)	—	May lead to hypokalemia; corticosteroids may exacerbate this effect; minor systemic absorption with aerosol administration; can be nebulized long term
	0.3–1 mg/mL × 15 minutes q6–12h	Most species
	7–10 mg/mL saline	Most species
Carbenicillin (Geocillin, Roerig)	20 mg/mL saline × 15 minutes q12h	Psittacines/*Pseudomonas* pneumonia; use in combination with parenteral aminoglycosides
Cefotaxime	10 mg/mL saline × 10–30 minutes q6–12h	Most species
Ceftriaxone	40 mg/mL sterile water	Poultry/PD
	40 mg/mL sterile water and DMSO	Poultry/PD; 1 g ceftriaxone in 10 mL sterile water, plus 15 mL DMSO
	200 mg/mL sterile water and DMSO	Poultry/PD; 4 g ceftriaxone in 10 mL sterile water, plus 10 mL DMSO
Clotrimazole (1%)	10 mg/mL propylene glycol or polyethylene glycol × 30–60 minutes q24h × 3 days, off 2 days, repeat PRN for up to 4 months	Most species/treatment of aspergillosis for stable patients without respiratory distress; can be toxic to psittacines at this dose; may use in combination with systemic amphotericin B, flucytosine, and itraconazole
	10% clotrimazole in propylene glycol with 5% DMSO	Raptors
Doxycycline hyclate	13 mg/mL saline	Psittacines
Enilconazole	0.2 mg/5 mL saline q12h × 21 days	Most species, including raptors, psittacines
	10 mg/mL sterile saline or water	Most species/antifungal (e.g., aspergillosis)
Enrofloxacin[b]	10 mg/mL saline	Most species
Gentamicin	3–6 mg/mL saline or sterile water and 1–2 mL acetylcysteine (20%) × 20 minutes q8h	Most species
	5 mg/mL saline × 15 minutes q8h	Most species
Lincomycin	250 mg/mL water	Most species
Miconazole	Nebulize 15 minutes q8h × 10 days	Raptors/aspergillosis
Oxytetracycline	2 mg/mL × 60 minutes q4–6h	Parakeets/PD
Piperacillin	10 mg/mL saline × 10–30 minutes q6–12h	Most species
Sodium chloride	—	Viscosity of respiratory secretions may be decreased by hydration
Spectinomycin	13 mg/mL saline	Most species
Sterile water	—	Viscosity of respiratory secretions may be decreased by hydration
Sulfadimethoxine	13 mg/mL saline	Most species
Terbinafine	500 mg and 1 mL acetyl-L-cysteine and 500 mL distilled water[46]	Psittacines/aspergillosis
Terbutaline	0.01 mg/kg with 9 mL saline	Psittacines/bronchodilation
Tylosin	10 mg/mL saline × 10–60 minutes q12h	Most species
	20 mg/mL DMSO or distilled water × 1 hour	Pigeons, quail (PD), most species
	20 mg/mL DMSO and 0.5 mL saline	Psittacines

[a]Nebulization is an adjunctive therapy indicated for rhinitis, sinusitis, tracheitis, pneumonia, airsacculitis, and syringeal aspergilloma, where there is air movement occurring in the patient's disease state; optimal particle size for deposition in the trachea is 2 to 10 μm; optimal particle size for peripheral airways is 0.5 to 5 μm; treatments of 30 to 45 minutes repeated q4–12h are recommended; caution: do not overhydrate airways.
[b]These drugs are banned in food-producing species in the United States as well as some other countries. Use with caution and follow local laws regarding administration to food animals.
DMSO, Dimethyl sulfoxide; *PD,* pharmacodynamic; *PRN,* as needed.

TABLE 9

Agents Used in the Treatment of Toxicologic Conditions

Agent	Dosage	Species/Comments
N-acetylcysteine	—	
	800 mg/kg/day in food[186]	Broiler chickens/aflatoxicosis
		Acetaminophen toxicosis; anecdotal
Bismuth subsalicylate	2–5 mg/kg PO once	Adsorbent; gavage; alternatively, can use activated charcoal
Botulinum antitoxin	0.05–1 mL/day	Treatment of botulism
Calcitonin	4 U/kg IM q12h	Most species/reduce hypercalcemia (e.g., that caused by cholecalciferol rodenticide toxicity)
Calcium EDTA (edetate calcium disodium) (CaEDTA)	—	Preferred initial chelator for lead and zinc toxicosis; may cause renal tubular necrosis in mammals; maintain hydration and monitor patient for polyuria/polydipsia; SC, IM absorbed well
	10–50 mg/kg IM q12h × 5–10 days or longer	Raptors
	20–70 mg/kg IV	Most species/empirical diagnosis; signs should resolve for up to 48 hours; diluted 1:4 in saline
	25–50 mg/kg IV q12h	Geese
	30–35 mg/kg IM, IV q8–12h × 3–5 days, off 3–4 days, repeat PRN	Most species
	40 mg/kg IM q12h	Cockatiels/PD; reduces lead levels when used alone or with DMSA
Charcoal, activated	—	Adsorbs toxins from the intestinal tract; may be mixed with hemicellulose to act as a bulk laxative to aid in the passage of ingested toxins; administration before cathartic use may help bind small particles of heavy metal; see magnesium hydroxide for combination
	52 mg/kg PO once	A component of oiled bird treatment; alternatively, may use bismuth
	2000–8000 mg/kg PO	Most species
Charcoal, activated/electrolyte slurry (ToxiBan, Vet-A-Mix)	—	Orally administered adsorbent for GI tract toxins
	50 mL/kg by gavage	Three bottles of charcoal slurry (3.75 g/kg) added to 250 mL of electrolyte solution; use in treatment of oiled birds
Deferiprone	—	Iron chelator; used in the treatment of hemochromatosis/iron storage disease
	50 mg/kg PO, IV once[197]	White leghorn chickens/PK; half-life of 3.2 hours following oral dose
	50 mg/kg PO, IV once[198]	King pigeons/PK; half-life of 2.98 hours following oral dose
	50–75 mg/kg PO q12h[199]	White leghorn chickens, king pigeons/no adverse effects noted at either dose
	75 mg/kg PO q24h[164]	Hornbills
	75 mg/kg PO q24 × 30 days[101]	Common mynahs; additional 30 days of treatment did not result in significant changes in liver iron content
	100 mg/kg PO q24h	
Deferoxamine	—	Iron chelator; used in the treatment of hemochromatosis/iron storage disease
	50 mg/kg IM q12h[66]	Chestnut-fronted macaw
	100 mg/kg SC q24h × 30 days[101]	Common mynahs; additional 30 days of treatment did not result in significant changes in liver iron content
	100 mg/kg IM q24h	

TABLE 9

Agents Used in the Treatment of Toxicologic Conditions—cont'd

Agent	Dosage	Species/Comments
Detergent (Dawn, Procter & Gamble)	1%–5% bath	Submerse bird up to mid-neck region; rinse with water; use water at 103–105°F (39–41°C) and 40–60 psi; use in treatment of oiled birds
Dimercaptosuccinic acid (DMSA)	—	Oral chelator for lead or zinc; may be effective for mercury toxicosis
	25–35 mg/kg PO q12h × 5 days/week × 3–5 weeks	Most species, including raptors/lead toxicosis
	25–35 mg/kg PO q24h × 10 days	Psittacines, raptors/lead and zinc toxicosis
	40 mg/kg PO q12h × 21 days	Cockatiels/PD; lead toxicosis; reduces lead levels when used alone or in combination with CaEDTA; 80 mg/kg resulted in death in >60% of cockatiels
Fluid therapy	—	Dehydration, shock, nutritional support, etc.
Intravenous lipid emulsion therapy	15 mL/kg/hour[114]	Domestic goose with oleander toxicosis; clinical signs resolved after 2 hours
Magnesium hydroxide (M) (Milk of Magnesia, Roxane)/activated charcoal (C)	(M) 10–12 mL + (C) 1 tsp powder	Most species/cathartic[a]; adsorbent
Oral electrolyte solutions (Pedialyte; Ross Labs)	30 mL/kg by gavage	Most species/at field stabilization site
Penicillamine	—	Preferred chelator for copper toxicosis; may be used for lead, zinc, and mercury toxicosis
	30 mg/kg PO q12h × ≥7 days	Most species/initially supplemented with CaEDTA once in severe neurological disease
	30–55 mg/kg PO q12h × 7–14 days	Most species, including raptors, waterfowl
	50–55 mg/kg PO q24h × 1–6 weeks	Most species, including psittacines, raptors/use in combination with CaEDTA for several days followed by penicillamine × 3–6 weeks
Pralidoxime	10–100 mg/kg q24–48h, or repeat once q6h	Binds to organophosphate-inactivated acetylcholinesterase; used in treatment of organophosphate or carbamate poisoning
Tea/tannins	8 g/kg of food	Reduced absorption of iron when fed to starlings; used in prevention of iron storage disease
Vitamin K_1	0.2–2.2 mg/kg IM q4–8h until stable, then q24h PO, IM × 14–28 days	Most species, including raptors/rodenticide anticoagulant toxicosis

[a]Cathartics increase gastrointestinal motility and are used to evacuate the gut and prevent absorption of toxins.
CaEDTA, edetate calcium disodium; *DMSA,* Dimercaptosuccinic acid; *EDTA,* ethylenediaminetetraacetic acid; *GI,* gastrointestinal; *IM,* intramuscular; *IV,* intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 10

Psychotropic Agents[a]

Agent	Dosage	Species/Comments
Amitriptyline	—	Tricyclic antidepressant; antihistaminergic action; used in the treatment of pruritic conditions (including feather-damaging behavior), anxiety disorders, and/or depression
	1–5 mg/kg PO q12–24h[191]	Most species/feather-damaging behavior, obsessive-compulsive disorders, phobias; doses up to 9 mg/kg may be required but may also cause adverse effects so titration to individual patient effect is recommended
	2 mg/kg PO q24h	Psittacines/minimum of 30 days
Buspirone	0.5 mg/kg PO q12h	Anxiolytic drug, used in the treatment of anxiety disorders
Carbamazepine	3–10 mg/kg PO q24h	Anticonvulsant; treatment of seizure disorders; may also be beneficial to treat feather-damaging behavior and anxiety- or frustration-related aggression
	166 mg/L drinking water	Most species/anticonvulsant; analgesic; may cause bone marrow suppression; combination with chlorpromazine or haloperidol recommended for the initial 2 weeks of the treatment
Chlorpromazine	—	Phenothiazine derivative; antipsychotic drug; dopamine antagonist (less specific than haloperidol); main effect is sedation, but may be useful for feather-damaging behavior as well
	0.1–0.2 mg/kg once (tranquilizer)	Cockatoos, ring-necked parakeets/use with carbamazepine after the removal of Elizabethan collar; mild sedation and decreases obsessive behaviors
	1 mL stock solution[b]/120 mL drinking water	Most species/mild sedation
	0.2–1 mL stock solution/kg q12–24h	Most species/mild sedation
Clomipramine	—	Tricyclic antidepressant; antihistamine; used, for example, in the treatment of impulsive and obsessive-compulsive disorders (ICD/OCD), depression and/or anxiety disorders
	0.5–1 mg/kg PO q12–24h	Psittacines/feather-damaging behavior; automutilation; start with low dose and gradually increase over 4–5 days
	3–5 mg/kg PO q12–24h	Psittacines/compulsive feather-damaging behavior or impulse control disorder; anxiety
	4–9.5 mg/kg PO q12h	Grey parrots/behavior interpreted as paradoxical anxiety; combine with anxiolytic therapy (buspirone)
Diazepam	—	Benzodiazepine sedative; anxiolytic/stress-associated feather picking; useful as sole agent or in combination with phenobarbital for seizure control
	0.25–0.5 mg/kg IM, IV q24h × 2–3 days	Raptors/appetite stimulant
	0.5 mg/kg PO	Passerines/calm fractious species
	0.5–0.6 mg/kg IM	Most species/facilitates acceptance of Elizabethan collar
	0.5–1(–1.5) mg/kg PO, IM, IV q8–12h	Most species/control of seizures
	2.5–4 mg/kg PO q6–8h	Psittacines/sedation
	10–20 mg/L drinking water	Most species
Diphenhydramine	—	Antihistamine; mild hypnotic effects; suspected allergic feather picking
	2–4 mg/kg PO q12h	Most species
	2 mg/L drinking water	Most species
Doxepin	—	Tricyclic antidepressant; antihistaminergic action; used in the treatment of pruritic conditions (including feather-damaging behavior), anxiety disorders, and/or depression
	0.5–1 mg/kg PO q12h	Most species/feather-damaging behavior
	1–2 mg/kg PO q12h	Psittacines/anxiety; pruritus
	1–5 mg/kg PO q24h	Psittacines/feather-damaging behavior
Fluoxetine	—	Selective serotonin reuptake inhibitor; antidepressant; adjunctive treatment for depression-induced feather picking
	0.4–4 mg/kg PO q24h	Psittacines/compulsive feather picking
	2–3 mg/kg PO q12–24h	Most species, including psittacines
	1 mg/kg PO q24h	Psittacines
	1–5 mg/kg PO q24h	Psittacines
Gabapentin	15–20 mg/kg q8–12h	Psittacines; modulating seizure activity
Haloperidol	—	Butyrophenone derivative; dopamine antagonist, antipsychotic drug
	0.1–0.2 mg/kg PO q12h	Psittacines/automutilation; feather-damaging behavior
	0.2–0.9 mg/kg PO q24h	Most species/stereotypic preening behavior
	1–2 mg/kg IM q14–21d	Most species, including psittacines

TABLE 10

Psychotropic Agents—cont'd

Agent	Dosage	Species/Comments
Hydroxyzine	—	Antihistamine; treatment of allergic responses, pruritus and pruritus-associated behavioral disorders
	2 mg/kg PO q8–12h	Most species/pruritus
	30–40 mg/L drinking water	Most species
Levetiracetam	50 mg/kg PO q8h or 100 mg/kg PO q12h[166]	Hispaniolan Amazon parrots/antiepileptic; potential use in long-term anticonvulsive treatment; drug levels should be monitored
Lorazepam	—	Benzodiazepine, tranquilizer/sedative; used in macaws with feather picking or aggression (may be used concurrently with haloperidol)
	0.1 mg/kg PO q12h	Macaws/aggression; feather-damaging behavior; use alone or with haloperidol
Naloxone	—	Opioid receptor antagonist, used in the acute treatment of stereotypies, compulsive, and self-injurious behaviors or addictions
	2 mg/kg IV	Psittacines/may be used to determine the response of stereotypic behavior to antagonist therapy; reduction of behavior should be observed within 20 minutes
Naltrexone	—	Opioid receptor antagonist, used in the acute treatment of stereotypies, compulsive and self-injurious behaviors or addictions
	1.5 mg/kg PO q8–12h	Most species/feather-damaging behavior; automutilation; contraindicated in patients with liver disease; may need to increase dosage 2× to 6× to be effective; dissolve tablet in 10 mL sterile water; preservative does not go into solution
Nortriptyline	—	Tricyclic antidepressant; may be beneficial for treating feather-damaging behavior, anxiety and/or depression. Hyperactivity commonly noted as side effect
	16 mg/L drinking water	Most species/feather-damaging behavior; seldom used; decrease dose or discontinue if hyperactivity develops; taper dose to discontinue
Paroxetine	—	Selective serotonin reuptake inhibitor, antidepressant, used in the treatment of depression, posttraumatic stress and panic disorders and ICD/OCD
	1–2 mg/kg PO q12–24h	Macaws, ibis/feather-damaging behavior; automutilation; generally, requires long-term therapy
	3 mg/kg PO q12h	Pigeons/reduce compulsive behavior
	4 mg/kg PO q12h[188]	Grey parrots/PK
Phenobarbital sodium	—	Barbiturate anticonvulsant; mild sedative effect; long-term seizure management; adjust dosage based on blood levels; may cause deep sedation and inability to perch
	1–5 mg/kg IV bolus	Most species/status epilepticus; begin at low end of dosage range and increase for refractory seizures
	2–7 mg/kg PO q8–12h	Most species/feather picking; seizures; self-mutilation
	17 mg/kg PO once[143]	Grey parrots/PK; half-life less than 2 hours
	50–80 mg/L drinking water	Most species, including Amazon parrots/idiopathic epilepsy
Potassium bromide	—	Long-term seizure management; use as sole agent or in conjunction with phenobarbital; monitor blood levels that may take up to 90 days to establish steady state; not available in approved dosage forms in North America; may be obtained from chemical companies or compounding pharmacies; for a concentration of 250 mg/mL, add distilled water as needed to 25 g of potassium bromide for a final volume of 100 mL
	25 mg/kg PO q24h	Most species
	50–80 mg/kg PO q24h	Pigeons
	75 mg/kg PO	Psittacines
Trazodone	30 mg/kg PO q24h[36]	Pigeons/PK; serotonin reuptake inhibitor, single dose resulted in plasma concentrations above therapeutic levels in humans for 20 hours
Zonisamide	20 mg/kg PO q8–12h	Psittacines/antiepileptic

[a]The use of psychotropic agents in birds is controversial because safety, efficacy, and pharmacologic effects are poorly documented; anxiolytics or tricyclic antidepressants may be useful for stereotypic behaviors or mutilation; selective serotonin reuptake inhibitors may prove helpful for explosive behaviors; consider metabolic scaling when calculating dosages; these treatments should be used as components of a structured behavior change strategy. Note: most of the dosages mentioned in this table have been derived from case reports and/or anecdotal evidence. As information on pharmacokinetics, pharmacodynamics, efficacy, and toxicity is currently lacking for most of these drugs, no specific recommendations can be made at this stage.

[b]Stock solution: 125 mg chlorpromazine in 31 mL simple syrup.

IM, Intramuscular; *IV,* intravenous; *PK,* pharmacokinetic; *PO,* oral.

TABLE 11
Nutritional/Mineral Support

Agent	Dosage	Species/Comments
Calcium	—	Recommended dietary levels[a]
	3–10 mg/kg feed (0.3%–1%)	Laying parrots
	4–8 mg/kg feed (0.4%–0.8%)	Growing Muscovy ducks
	8 mg/kg feed (0.8%)	Growing Japanese quail
	8–10 mg/kg feed (0.8%–1%)	Growing chickens
	18.8–32.5 mg/kg feed (1.88%–3.25%)	Laying chickens/3.25% recommended for hens that lay eggs daily
	22.5 mg/kg feed (2.25%)	Laying turkeys
Calcium borogluconate (10%)	50–100 mg/kg IM, IV	Psittacines/20% solution
	100–500 mg/kg SC, IV (slow) once	Raptors/hypocalcemia
Calcium glubionate	25–150 mg/kg PO q12h	Most species/hypocalcemia, calcium supplementation
Calcium gluconate (10%)	—	Hypocalcemia; dilute 1:1 with saline or sterile water for IM or IV injections
	5–10 mg/kg SC, IM, IV (slow) q12h PRN	Psittacines/hypocalcemic tetany
	10–100 mg/kg IM	Psittacines/acute presentation of hypocalcemia
	25–50 mg/kg SC, IV (slow)	Pigeons
	50–100 mg/kg IM (diluted), IV (slow)	Most species, including psittacines, pigeons, raptors
	1 mL/30 mL (3300 mg/L) drinking water	Psittacines/calcium supplementation
Calcium lactate/calcium glycerophosphate	5–10 mg/kg IM q7d PRN	Most species, including raptors/hypocalcemia
	50–100 mg/kg IV (slow bolus) once	Grey parrots
Dextrose (50%)	50–100 mg/kg IV (slow bolus) to effect	Psittacines/hypoglycemia; can dilute with fluids
	500–1000 mg/kg IV (slow bolus)	Hypoglycemia; can dilute with fluids
Essential fatty acids (omega-3, omega-6)	0.2–0.5 mL/kg PO q24h	Most species; antiinflammatory, immunomodulation
Hemicellulose (Metamucil, Searle)	Small amount on food daily	Most species/for bulk in diet; facilitates defecation in bowel deficit disorders and other conditions
	0.5 tsp/60 mL hand-feeding formula or baby food gruel	Psittacines/bulk diet to delay absorption of an ingested toxin
Iodine (Lugol's iodine)	0.2 mL/L drinking water daily	Most species/thyroid hyperplasia
	2 parts iodine + 28 parts water; 3 drops into 100 mL drinking water	Budgerigars/thyroid hyperplasia
Iron	20–40 mg/kg feed	Toucans/levels recommended for a low-iron diet
Iron dextran	10 mg/kg IM, repeat in 7–10 days PRN	Most species/iron deficiency anemia; use cautiously in species in which iron storage disease is common
Lactobacillus (Bene-Bac, Pet-Ag)	1 pinch/day/bird	Psittacines/stimulation of normal gastrointestinal flora regrowth
	1 tsp/L hand-feeding formula	Most species
Magnesium sulfate	20 mg/kg IM	Grey parrot/dietary hypomagnesemia and seizures
Pancreatic enzyme powder (Viokase-V Powder, Fort Dodge)	—	Most species/exocrine pancreatic insufficiency; maldigestion; mix with food and let stand 30 minutes
	2–5 g/kg	Most species
	$^1/_8$ tsp/kg feed	Most species
	$^1/_8$ tsp/60–120 g lightly oil-coated seed	Most species
	$^1/_8$ tsp/30–120 mL hand-feeding formula PRN	Psittacine neonates
Potassium chloride	0.5 mEq/kg PO q12h	Most species/hypokalemia
Selenium (Se)	0.05–0.1 mg Se/kg IM q3–14d	Most species/neuromuscular diseases (capture myopathy, white muscle disease, some cardiomyopathies); may be useful in some cockatiels with jaw, eyelid, and tongue paralysis
Vitamin A	200 U/kg IM	Raptor juveniles/supplemental therapy for pox infection
	2000 U/kg PO, IM	Psittacines/adjunctive therapy for pox infection
	5000 U/kg IM q24h × 14 days, then 250–1000 IU/kg q24h PO	Psittacines/adjunctive therapy for respiratory or epithelial disease
	20,000–33,000 U/kg IM q7d	Most species/hypovitaminosis A; maximum dose; improves skin healing

TABLE 11

Nutritional/Mineral Support—cont'd

Agent	Dosage	Species/Comments
Vitamin B_1 (thiamine)	—	Thiamine deficiency: requirements may be higher if thiaminase is present in diet[b]
	1–2 mg/kg PO q24h	Raptors, penguins, cranes/daily supplement
	1–2 mg/kg IM q24h	Vultures, raptors, cranes, penguins/CNS signs
	1–3 mg/kg IM q7d	Most species, including raptors
	1–50 mg/kg PO q24h × 7 days or indefinitely	Raptors
	3–30 mg/kg IM q7d	Raptors/stimulates appetite, hematopoiesis; neuromuscular disease; liver disease; supportive therapy; adjunct to sulfa therapy
	25–30 mg/kg feed or fish	Piscivorous species/recommended level of supplementation
	2850 mg/L drinking water q7d	Pigeons
Vitamin B_6 (pyridoxine)	5 mg/kg IM or 25 mg/kg PO once[161]	Maximum nonlethal dose in falcons
Vitamin B_{12} (cyanocobalamin)	0.25–0.5 mg/kg IM q7d	Most species/anemia
	2–5 mg/bird SC	Pigeons/vitamin B_{12} deficiency
Vitamin B complex	—	Usually dosed based on thiamine (see vitamin B_1)
Vitamin D_3	3300 U/kg IM q7d PRN	Most species/hypovitaminosis D_3; hypervitaminosis D may occur with excessive use
	6600 U/kg IM once	Most species
	11–30 minutes of direct sunlight/day	Chickens/sufficient for endogenous synthesis of vitamin D
Vitamin E	0.06 mg/kg IM q7d	Psittacines/hypovitaminosis E
	0.06 mg/kg IM	Ratites/prevention or treatment of capture myopathy
	15 mg/kg PO once	Raptors/PD; administer without food
	200–400 mg/bird PO q24h	Great blue herons
	100 mg/kg fish (wet basis)	Piscivorous species/recommended level of supplementation
Vitamin K_1 (phytonadione)	0.025–2.5 mg/kg IM q12h	Most species
	0.2–2.2 mg/kg IM q4–8h until stable, then q24h × 14 days	Most species/rodenticide toxicity
	2.5 mg/kg IM q24h until hemostasis, then q7d PRN	Psittacines/vitamin K responsive disorders; hematochezia; coagulopathy
	10–20 mg/kg IM q12–24h	Psittacines
	0.1 mg/kg feed	Turkeys/PD; as effective as 1–2 mg/kg in reducing plasma prothrombin time

[a]Grains and seeds commonly fed to parrots contain calcium levels of approximately 0.02% to 0.1% dry matter (DM).
[b]Food items known to contain appreciable amounts of thiaminase include clams, herring, smelt, and mackerel.
CNS, Central nervous system; *IM,* intramuscular; *IV,* intravenous; *PD,* pharmacodynamic; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 12

Ophthalmologic Agents

Agent	Dosage	Species/Comments
Bacitracin/neomycin/ polymyxin B sulfate	Small bead topical	Most species/antibiotic; corneal ulcers, conjunctivitis
Chloramphenicol ophthalmic drops[a]	1 drop topical q6–8h	Most species, antibiotic
Ciprofloxacin HCl[a]	1 drop topical q4–8h	Most species/antibiotic; corneal ulcers, conjunctivitis (e.g., *Chlamydophila, Mycoplasma*)
	One drop topical q12h; use in conjunction with tylosin 1 mg/mL drinking water × 21–77 days	House finches/*Mycoplasma gallisepticum* conjunctivitis
Dexamethasone (0.1%) ophthalmic drops	1 drop topical q4–8h	Most species/traumatic, noninfectious uveitis; may suppress adrenocortical function so antifungal and antibiotic prophylaxis may need to be considered
Diclofenac sodium 0.1% ophthalmic solution	1 drop OU q12h × 7 days[76]	Chickens/PK; diclofenac detectable in plasma with no biochemistry changes noted
Flurbiprofen ophthalmic solution	Topical as indicated	NSAID used in the eye to treat or prevent inflammation (i.e., uveitis, conjunctivitis)
Gentamycin sulfate	1 drop topical q4–8h	Most species/antibiotic; corneal ulcers; may cause irritation
Miconazole	1 drop topical q12h	Parrots/fungal keratitis
Neomycin/polymyxin B/ gramicidin	1 drop topical q2–8h	Most species/antibiotic; corneal ulcers; conjunctivitis
Oxytetracycline/ polymyxin B	Small bead topical	Most species/antibiotic; conjunctivitis
Prednisolone acetate (1%)	1 drop q4–8h	Raptors/traumatic anterior uveitis without corneal ulceration
Proparacaine (0.5%)	Topical	Topical anesthesia
Rocuronium bromide	—	Neuromuscular blocking agent
	0.12 mg topical in each eye[11]	European kestrels/mydriatic agent; maximal mydriasis was achieved in 90 minutes
	20 µL/eye[6,139]	Hispaniolan Amazons/first effects noted at 8 minutes; lasted 6 hours
Tetracaine (6%)	Topical	Topical anesthetic
Vecuronium	—	Neuromuscular blocking agent; mydriatic
	0.08 mg topically per eye[122,147]	European kestrels, psittacines
	0.16 mg topically per eye[113]	Double-crested cormorants

[a]These drugs are banned in food-producing species in the United States as well as some other countries. Use with caution and follow local laws regarding administration to food animals.
NSAID, Nonsteroidal antiinflammatory drug; *PK,* pharmacokinetic.

TABLE 13

Agents Used in Emergencies

Agent	Dosage	Species/Comments
Aminophylline	4 mg/kg PO q6–12h	Can give orally after initial response
	10 mg/kg IV q3h	Use for pulmonary edema
Atropine sulfate	0.2–0.5 mg/kg IM, IV, IO	Bradycardia; CPR
Calcium gluconate	50–100 mg/kg IM, IV (slow bolus)	Hypocalcemia; dilute to 50 mg/mL; hyperkalemia
Dexamethasone Na phosphate	2–6 mg/kg IM, IV q12–24h	Head trauma (until signs abate); shock (1 dose); hyperthermia (until stable); use in these conditions is controversial
Dextrose (50%)	50–100 mg/kg IV (slow bolus to effect)	Hypoglycemia; can dilute with fluids
	500–1000 mg/kg IV (slow bolus)	Hypoglycemia; can dilute with fluids
Dextran 70	10–20 mL/kg	Most species/hypovolemic shock; colloid with a t½ shorter than hetastarch
Diazepam	0.5–1 mg/kg IM, IV PRN	Seizures
Doxapram	5–20 mg/kg IM, IV, IO	Most species/respiratory depression or arrest; CPR
Epinephrine (1:1000)	0.5–1 mL/kg IM, IV, IO, intratracheal	CPR; bradycardia
Fluids	10–25 mL/kg IV, IO	Bolus over 5–7 minutes
	50–90 mL/kg fluids SC,[a] IV, IO	Most species
Hetastarch	10–15 mL/kg IV (slow) q8h × 1–4 treatments	Most species, including raptors/hypoproteinemia; hypovolemia
Mannitol	0.2–2 mg/kg IV (slow) q24h	Raptors/cerebral edema; anuric renal failure; contraindicated in intracranial bleeding
Magnesium sulfate	20 mg/kg IM once[105]	Grey parrot/treatment for seizure activity associated with hypomagnesemia (associated with hypocalcemia that is not responsive to calcium therapy)
Prednisolone Na succinate	10–20 mg/kg IM, IV q15min PRN	Historically it has been used for head trauma and CPR; use in these conditions is controversial; no longer appears to be a treatment for traumatic brain injury and may actually exacerbate mortality
	15–30 mg/kg IV	Raptors/see the previous comment
Sodium bicarbonate	1 mEq/kg q15–30min to maximum of 4 mEq/kg total dose	Metabolic acidosis
	5 mEq/kg IV, IO once	CPR
Terbutaline	0.01 mg/kg PO, IM q6h	Psittacines/α2-selective smooth muscle bronchodilator
	0.1 mg/kg PO q12–24h	Macaws, Amazon parrots/bronchodilator; obstructive pulmonary disease, pneumonitis

[a]Because of the presence of peripheral vasoconstriction, subcutaneous administration is not adequate for patients in shock.
CPR, Cardiopulmonary resuscitation; *IM,* intramuscular; *IO,* intraosseous; *IV,* intravenous; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 14
Cardiovascular/Respiratory Agents

Agent	Dosage	Species/Comments
Acetylsalicylic acid (aspirin)	5 mg/kg PO q48h	Most species/antithrombotic agent
Aminophylline	4–5 mg/kg PO, IM, IV q6–12h	Most species/bronchodilator; need to prepare as a suspension daily
	8–10 mg/kg PO, IM, IV q6–8h	Raptors, ratites
	10 mg/kg IV q3h, then PO after initial response	Most species
	10 mg/kg IM, IV q8–12h	Most species/for IV use, dilute in 10–20 mL saline or 5% dextrose in water and inject slowly
Atenolol	5–10 mg/kg PO q12–24h	Most species/negative inotrope, lowering blood pressure
Atorvastatin	10–20 mg/kg PO q12h	Parrots/hypercholesterolemia; use is controversial
Benazepril	0.5 mg/kg PO q24h[61,169]	Parrots/angiotensin-converting enzyme (ACE) inhibitor, vasodilation
Bromhexine	1.5–6 mg/kg IM q12–24h	Most species/expectorant
Carvedilol	1–9 mg/kg PO q12–24h[61]	Parrots/negative inotrope
Digoxin	—	Congestive heart disease: toxic reactions include depression, ataxia, vomiting, diarrhea; contraindicated with renal or liver disease; monitoring of serum digoxin, potassium, magnesium, calcium, and ECG is recommended; induced arrhythmias in pigeons at 0.2 mg/kg/day
	0.0035 mg/kg IV q24h	Turkeys
	0.0049 mg/kg IV q12h	Poultry
	0.01 mg/kg PO q24h × 6 weeks	Chickens/ascites syndrome; reduced ascites; no apparent toxicity
	0.01–0.02 mg/kg PO q12h	Psittacines, passerines, raptors/congestive heart disease
	0.02 mg/kg PO q24h × 5 days	Parakeets, sparrows (PD)/this dose led to signs of toxicity in a mynah
	0.05 mg/kg PO q24h	Quaker parakeets/PD; congestive heart failure; cardiomyopathy
	0.13 mg/L drinking water	Psittacines, passerines, raptors/congestive heart disease
Diltiazem	1–2 mg/kg PO q8–12h[37]	Most species/calcium channel blocker, used to lower blood pressure
	15 mg/kg PO q12h[202]	Chickens
Enalapril	0.25–0.5 mg/kg PO q24–48h	Most species/dilated cardiomyopathy; monitor uric acid levels; reduce dose or discontinue if concurrent renal disease
	1.25 mg/kg PO q8–12h	Pigeons, Amazon parrots/PK
	2.5–5 mg/kg PO q12h	Amazon parrot/right-sided heart failure; long-term therapy
Furosemide	—	Diuretic; overdose can cause dehydration and electrolyte abnormalities; toxicity characterized by neurologic signs and death
	0.1–2 mg/kg PO, SC, IM, IV q6–24h	Most species, including psittacines, raptors; lories are extremely sensitive
	0.15 mg/kg IM q8h	Mynahs/ascites, hemochromatosis
	0.5–2.2 mg/kg PO, IM q12–24h	Most species/cardiac disease, ascites
	2–5 mg/kg PO, IM q12–24h	Raptors/cardiac disease, pulmonary congestion
	2.5–10 mg/kg PO q12h × 7–14 days	Cockatiels, budgerigars/ascites
	40 mg/L drinking water	Most species/congestive heart failure; can be used with digoxin and ACE inhibitors
Isoxsuprine	10 mg/kg PO q12–24h[61,174]	Psittacines/vasodilator
Pentoxifylline	15–30 mg/kg q8–12h PO	Most species/peripheral arterial disease, frostbite, wing tip edema
Pimobendan (Vetmedin, Boehringer-Ingelheim)	—	Phosphodiesterase inhibitor and calcium sensitizer used in treatment of congestive heart failure
	10 mg/kg PO[79]	Hispaniolan Amazon parrots/use tablet suspension; safety and efficacy are unknown; potential use in other birds is unknown
Propranolol	0.04 mg/kg IV (slow) 0.2 mg/kg IM	Most species/supraventricular arrhythmia, atrial flutter, fibrillation
Rosuvastatin	10–25 mg/kg PO[12]	Psittacines/hypercholesterolemia; doses did not result detectable plasma concentrations
Salbutamol	0.1–0.2 mg/kg q8–12h PO, IM	Most species/bronchodilator; anecdotal information
Sildenafil	1–5 mg/kg PO q8–12h[17,61]	Parrots/phosphodiesterase inhibitor, vasodilator, used to treat pulmonary hypertension
	1 mg/kg PO q12h[31]	African penguin/used in treatment of right-sided heart failure
Spironolactone	1–2 mg/kg PO q12h[51,61,169]	Psittacines, chickens/diuretic
Terbutaline	0.01 mg/kg PO, IM q6h	Psittacines/α2-selective smooth muscle bronchodilator
	0.1 mg/kg PO q12–24h	Macaws, Amazon parrots/bronchodilator; obstructive pulmonary disease; pneumonitis
Theophylline	2 mg/kg PO q12h	Severe macaws/bronchodilation

ACE, Angiotensin-converting enzyme; *ECG,* electrocardiogram; *IM,* intramuscular; *IV,* intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PO,* oral; *SC,* subcutaneous.

TABLE 15

Dermatologic Agents

Agent	Dosage	Species/Comments
Armor All Protectant (Armor All-Protectant Corp.)	Topical to affected plumage	Most species/softens sticky trap glue-covered plumage; use detergent (Dawn) to remove Armor All
Bismuth subsalicylate (Pepto Bismol, Procter & Gamble)	1–2 mL/kg PO q12h 2–5 mL/kg PO once	Most species/weak adsorbent, demulcent Most species/a component of oiled bird treatment; alternatively can use activated charcoal
Chlorhexidine (0.05%–0.1% solution)	Topical	Presurgical skin cleaner; antiseptic
Povidone iodine	Topical, wash off within 5 minutes	Raptors/wound cleansing; antiseptic; but is infrequently used in avian dermatology owing to its drying, irritating, and staining effects
Skin-So-Soft (Avon)	Topical to affected plumage	Most species/softens and removes sticky trap glue from plumage; use Dawn dish detergent to remove Skin-So-Soft product[a]
Tincture of iodine	Topical	Most species, raptors/wounds
Trypsin-balsam of Peru-castor oil (Granulex, Pfizer)	Topical	Most species/digests necrotic tissue (may have debriding action); may have analgesic effects; may cause local inflammation and pyogenic reaction; do not use for long-term management[a]
Yeast cell derivatives (Preparation H, WhiteHall)	Topical q24h	Most species/pododermatitis; stimulation of epithelialization

[a]Many topical agents contain oils that adhere to plumage. These agents should be used sparingly and generally in nonfeathered regions to prevent losing the insulative properties of the plumage.
PO, Oral.

TABLE 16

Agents Used in the Treatment of Renal Disease

Agent	Dosage	Species/Comments
Allopurinol	10–30 mg/kg PO q12–24h	Most species/xanthine oxidase inhibitor used in the treatment of gout. Use is controversial
	25 mg/kg PO q24h[171]	Chickens/PD; reduced uric acid levels
	25 mg/kg PO q24h[115,142]	Red-tailed hawks/PD; no significant effect on plasma uric acid levels, while toxicity with secondary renal dysfunction was observed at 50 mg/kg
Colchicine	0.04–0.2 mg/kg PO q12–24h[43]	Most species/xanthine dehydrogenase inhibitor; may be used to treat amyloidosis and limit renal or hepatic fibrosis, but no controlled studies available
	0.18 mg/kg PO q24h[176]	Turkey/dose failed to influence uric acid levels after 7 days
Rasburicase	0.5 mg/kg IM[126]	Grey parrot/recombinant urate oxidase; uric acid levels significantly decreased 16–24 hours following injection
Urate oxidase/uricase (Uricozyme, Sanofi Winthrop)	100–200 U/kg IM q24h[142,172]	Red-tailed hawks, pigeons/PD; significantly lowered plasma uric acid, including postprandial plasma uric acid

IM, Intramuscular; *PD,* pharmacodynamic; *PO,* oral.

TABLE 17

Gastrointestinal and Hepatic Agents

Agent	Dosage	Species/Comments
Aluminum hydroxide	30–90 mg/kg PO q12h	Most species/antacid; phosphate binder
Cimetidine	—	Prototype histamine-2 blocker used to reduce gastrointestinal (GI) acid production
	3–10 mg/kg PO, IM, IV q8–12h	Ratites
	5 mg/kg PO, IM q8–12h	Psittacines/proventriculitis; gastric ulceration
Cisapride	0.5–1.5 mg/kg PO q8–12h	Most species/GI prokinetic agent, stimulates motility; not commercially available in the United States; can be compounded
Famotidine	1 mg/kg IM q12h[29]	Parrots/antacid; anecdotal information
Kaolin/pectin	2 mL/kg PO q6–12h	Psittacine neonates/intestinal protectant, antidiarrheal
	≤15 mL/kg PO, repeat PRN	Raptors
Lactulose	—	Reduces blood ammonia levels; does not treat liver disease
	150–650 mg/kg (0.2–1 mL/kg) PO q8–12h	Most species, including psittacines/hepatic encephalopathy
	200 mg/kg (0.3 mL/kg) PO q8–12h	Psittacine neonates
Magnesium hydroxide (M)/activated charcoal (C)	(M) 10–12 mL + (C) 1 tsp powder	Most species/cathartic; adsorbent
Magnesium sulfate (Epsom salts)	0.25–1 g/kg PO q24h × 1–2 days	Most species/purgative, cathartic; may cause lethargy; see peanut butter for combination
Mannitol	0.25–2 mg/kg q24h IV (slow bolus)	Most species/osmotic diuretic used to treat cerebral edema, especially after head trauma; may be used with furosemide
Maropitant	1 mg/kg SC, IM, PO q12–24h	Parrots/antiemetic, used to treat visceral pain, motion sickness
Metoclopramide	—	GI motility disorders; regurgitation; slow crop motility; no alterations in motility observed after a single dose of 1 mg/kg IM
	0.3 mg/kg PO, IM, IV	Most species
	0.5 mg/kg PO, IM, IV q8–12h	Most species, including psittacines/GI ileus; regurgitation
	2 mg/kg IM, IV q8–12h	Raptors, waterfowl/crop stasis; ileus
	12.5 mg/kg PO	Ratites/GI disorders
Mineral oil	5–10 mL/kg PO via gavage	Most species/cathartic; used to aid passage of grit and other foreign bodies; administer directly into the crop because oral administration may result in aspiration pneumonia; see peanut butter for combination
Mirtazapine	1 mg/kg PO q12–24h	Most species/appetite stimulant
Omeprazole	1–10 mg/kg PO q12h[27]	Most species/anecdotal information
	20–50 mg/kg PO q24h[94]	Chickens/omeprazole reduced gastroenteral toxicity at 20 mg/kg/day and almost completely prevented problems at 50 mg/kg/day
Peanut butter	Peanut butter and mineral oil (2:1)	Most species/add to diet; cathartic
	Dilute peanut butter and magnesium sulfate	Most species/add to diet; cathartic; dilute with water
Psyllium (Metamucil, Procter & Gamble)	0.5 tsp/60 mL hand-feeding formula	Most species/bulk diet; can use mineral oil as alternative or in addition to psyllium
Ranitidine	5 mg/kg PO q12h	Most species/antacid; anecdotal information
Silymarin (milk thistle)	50–75 mg/kg PO q12h	Most species/hepatic antioxidant; use in patients with liver disease and as ancillary to chemotherapy; use a low-alcohol or alcohol-free liquid formulation
Sucralfate	25 mg/kg PO q8h	Most species/oral, esophageal, gastric, duodenal ulcers; give 1–2 hours before food or other drugs; up to 200 mg/kg used anecdotally without adverse effects

GI, Gastrointestinal; *IM,* intramuscular; *IV,* intravenous; *PO,* oral; *PRN,* as needed; *SC,* subcutaneous.

TABLE 18
Chemotherapeutic Agents

Agent	Dosage	Species/Comments
L-Asparaginase	—	Antimetabolite, used in the treatment of lymphoma and immune-mediated diseases. Anaphylaxis and pancreatitis have been associated with use of L-asparaginase. Monitor patients for anaphylaxis and myelosuppression
	400 U/kg IM q7d[64]	Moluccan cockatoo/lymphosarcoma
	400 U/kg SC once[175]	Black swan/chronic lymphocytic leukemia
	1650 U/kg IM once[157]	Great horned owl/histiocytic sarcoma
Bleomycin	—	Antitumor antibiotic
	0.25 mg intralesionally as part of electrochemotherapy, 2 doses 2 weeks apart[110]	Budgerigar/epithelioid hemangioendothelioma
	0.5–1 mg/kg intralesionally as part of electrochemotherapy[146]	Cockatiel/uropygial gland squamous cell carcinoma
Carboplatin	—	Platinum product, used to treat osteosarcoma, carcinoma, other sarcomas, and mesothelioma. Monitor for myelosuppression and GI and renal toxicity. While not as toxic for the kidneys as cisplatin, caution is advised when using carboplatin in patients with renal insufficiency
	5 mg/kg IV, IO infused over 3 minutes[60,116]	Sulphur-crested cockatoos/PK Budgerigar/renal adenocarcinoma
	5 mg/kg IV[2]	ISA brown layer hens, call ducks, racing pigeons, English budgerigars/PK
	15 mg/kg IV q5wk[24]	Mallard duck/Sertoli cell tumor
	20 mg in 2 mL sesame oil intralesionally[100]	Greylag goose/atypical papilliform xanthomatous neoplasia
	125 mg/m^2 IV as a slow bolus, q14–21d[208]	Yellow-naped Amazon/bile duct carcinoma
	4.6 mg impregnated into calcium-matrix beads placed intralesionally[163]	Kori bustard/myxosarcoma
Chlorambucil	—	Alkylating agent, used most commonly for the treatment of lymphoma, lymphoblastic leukemia, and mast cell tumors. Occasionally combined with doxorubicin to treat mammary carcinoma and soft tissue sarcomas. Monitor for bone marrow depression, GI toxicity, and hepatotoxicity
	1 mg/bird PO 2×/week[133]	Pekin duck/lymphocytic leukemia
	1 mg/kg PO 2×/week[91]	Green-winged macaw/chronic lymphocytic leukemia; discontinued after 6 weeks due to thrombocytopenia
	2 mg/bird PO q48h[176]	Black swan/chronic lymphocytic leukemia
	2 mg/bird PO 2×/week[117]	Great horned owl/disseminated lymphoma; solid tumor increased in size despite therapy
	2 mg/kg PO 2×/week[73,135,153,204]	Umbrella cockatoo/cutaneous B-cell lymphoma Double yellow-headed Amazon/chronic lymphocytic leukemia; no apparent effect after 40 days Java sparrow/thymic lymphoma Cockatiel/chronic T-cell lymphocytic leukemia
Cisplatin	—	Platinum product, used to treat osteosarcoma, carcinoma, other sarcomas, and mesothelioma. Monitor for myelosuppression and GI and renal toxicity.
	0.2 mg/kg intralesionally in a sesame oil suspension[56]	African penguin/squamous cell carcinoma
	1 mg/kg IV over 1 hour[59]	Sulphur-crested cockatoos/PK
	30 mg/m^2 intralesionally (Manucy et al.)[212]	Buffon's macaw/squamous cell carcinoma
	1 mg cisplatin/cm^3 tumor intralesionally, mixed with sesame oil at a concentration of 10 mg/mL, 1×/week × 4 treatments[75]	Use powdered cisplatin rather than commercial injectable solution for better potency
Cyclophosphamide	—	Alkylating agent, used most commonly for the treatment of lymphoma, lymphoblastic leukemia, and mast cell tumors. Occasionally combined with doxorubicin to treat mammary carcinoma and soft tissue sarcomas. Side effects reported experimentally in birds include heteropenia, generalized bone marrow suppression, reversible changes in the liver and feather lesions[58,65,151]
	5 mg/kg PO q24h × 4 days, then 3 days off, then repeat[91]	Green-winged macaw/chronic lymphocytic leukemia
	10 mg/m^2 PO q24h[163]	Kori bustard/myxosarcoma
	200 mg/m^2 IO q7d[64]	Moluccan cockatoo/lymphosarcoma Great horned owl/histiocytic sarcoma

Continued

TABLE 18
Chemotherapeutic Agents—cont'd

Agent	Dosage	Species/Comments
Doxorubicin (Adriamycin)	—	Antitumor antibiotic, used for a wide variety of tumors, including osteosarcoma, mesenchymal and epithelial tumors, leukemias, and lymphomas. Can lead to severe perivascular sloughing if extravasated. Monitor for anaphylaxis, myelosuppression, GI toxicity, renal toxicity, and cardiotoxicity. Cardiomyopathy has been induced experimentally using doxorubicin in turkey poults[32]
	2 mg/kg IV[71]	Sulphur-crested cockatoos/PK
	30 mg/m^2 IO q2d[64]	Moluccan cockatoo/lymphosarcoma
	60 mg/m^2 IV q30d[40]	Blue-fronted Amazon/osteosarcoma
Lomustine (CCNU)	—	Alkylating agent
	60 mg/m^2 PO q3wk[175]	Black swan/chronic lymphocytic leukemia
Vincristine	—	Vinca alkaloid, used to treat lymphoma and other lymphoid tumors, mast cell tumors, and some sarcomas. Toxicities are usually mild, but monitoring for anaphylaxis, GI toxicity, and myelosuppression is warranted
	0.1 mg/kg IV q7–14d[153]	Umbrella cockatoo/cutaneous B-cell lymphoma
	0.5 mg/m^2 IV, then 0.75 mg/m^2 q7d × 3 treatments[133]	Pekin duck/lymphocytic leukemia and malignant lymphoma
	0.75 mg/m^2 q7d × 3 treatments[64]	Moluccan cockatoo/lymphosarcoma

GI, Gastrointestinal; *IM,* intramuscular; *IO,* intraosseous; *IV,* intravenous; *PD,* pharmacodynamic; *PK,* pharmacokinetic; *PO,* oral; *SC,* subcutaneous.

TABLE 19
Miscellaneous Agents

Agent	Dosage	Species/Comments
Anticoagulant citrate dextrose (A-C-D Solution, Sanofi)	0.15 mL/1 mL whole blood	Anticoagulant for transfusions; not effective for extended storage of whole blood; heparin can be substituted if A-C-D is not available
Citrate phosphate dextrose adenine solution (CPDA)	1 part CPDA:5 parts whole blood	Most species/anticoagulant for blood collection for transfusion; not for extended storage of whole blood
Cyclosporine	10–20 mg/kg PO q12–24h	Most species/immunosuppressant, used to treat autoimmune disorders (e.g., immune-mediated hemolytic anemia) and bornaviral-induced inflammation. Efficacy remains controversial at this time
Diphenhydramine	1–4 mg/kg PO q8–12h	Psittacines/allergic rhinitis, hypersensitivity, pruritus
	2 mg/kg IV, IO once	Cockatoos/used before chemotherapy
	2–4 mg/kg PO, IM, IV q12h	Most species/has calming effect in some anxious birds; may cause hypotension
	20–40 mg/L drinking water	Most species
Ferric subsulfate	Topical	Most species/hemostasis of bleeding nail or beak tip; will cause necrosis if used on open skin lesions
Fluids	PO, SC, IV as needed	Fluid requirement for most birds is 50 mL/kg/day
Gadopentetate dimeglumine (Magnevist, Berlex)	0.25 mmol/kg IV	Contrast agent for magnetic resonance imaging
Heparin	2 U/mL whole blood	Anticoagulant for blood transfusions
Hetastarch (Hespan, DuPont)	—	Colloid with a t½ of 25 hours; use with caution in patients suffering from congestive heart failure or renal failure
	10–15 mL/kg IV q8h × 1–4 treatments	Most species/chronic hypoproteinemia; decrease fluid treatment to ⅓–½ maintenance fluid dose
Hydroxyzine (Atarax, Roerig)	2–2.2 mg/kg PO q8h	Allergic pruritus; feather picking; self-mutilation
	34–40 mg/L drinking water	Most species/respiratory allergy; feather picking
Iohexol (Omnipaque, Sanofi Winthrop)	25–30 mL/kg PO	Cockatoos, Amazon parrots/gavage; radiographic gastrointestinal iodinated contrast media; 1:1 dilution with water can also be used
	50 mL/kg PO	Quaker parakeets, budgerigars
Pentobarbital sodium	0.2–1 mL/kg IV, ICe	Most species/euthanasia agent; birds may react unpredictably with IV administration; ICe administration is smooth, quiet
T61	0.03 mg/kg IV[9]	Most species/euthanasia agent; should only be used in unconscious or anesthetized birds

ICe, Intracoelomic; *IM,* intramuscular; *IO,* intraosseous; *IV,* intravenous; *PO,* oral; *SC,* subcutaneous.

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Units	Packed Cell Volume (%) Mean	 Range	White Blood Cell Count C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Mean	 Range	Heterophils C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Mean	 Range
Macaw group	5338	Conventional			15.2	10–20	9.5912	7.6–11.4
Mostly *Ara*, some *Anodorhynchus*		S.I.			15.2	10–20	9.5912	7.6–11.4
		%	48.5	42–56			63.1	50–75
Macaw, blue-and-gold	1367	Conventional			12.8	8–16	7.7568	6.272–9.088
(Blue-and-yellow macaw)		S.I.			12.8	8–16	7.7568	6.272–9.088
Ara ararauna		%	48.7	44–55			60.6	49–71
Macaw, green-winged	347	Conventional			14.2	11–16	8.9602	6.958–10.366
(Red-and-green macaw)		S.I.			14.2	11–16	8.9602	6.958–10.366
Ara chloropterus		%	47.2	42–54			63.1	49–73
Macaw, military	88	Conventional			16.5	12–20	11.8305	9.57–14.025
Ara militaris		S.I.			16.5	12–20	11.8305	9.57–14.025
		%	46.8	44–51			71.7	58–85
Macaw, scarlet	146	Conventional			12.5	10–14	7.525	6–9.125
(Red-and-yellow macaw)		S.I.			12.5	10–14	7.525	6–9.125
Ara macao		%	49.1	45–55			60.2	48–73
Macaw, severe	104	Conventional			12.1	9–14	7.3931	5.445–9.68
(Chestnut-fronted macaw)		S.I.			12.1	9–14	7.3931	5.445–9.68
Ara severus		%	49.1	45–55			61.1	45–80
Macaw, Hahn's	51	Conventional			14.1	10–18	7.5999	5.781–10.152
(Red-shouldered macaw)		S.I.			14.1	10–18	7.5999	5.781–10.152
Diopsittaca nobilis nobilis		%	51.3	47–55			53.9	41–72
Macaw, noble	22	Conventional			14.6	8–22	7.2708	4.964–9.198
(Red-shouldered macaw)		S.I.			14.6	8–22	7.2708	4.964–9.198
Diopsittaca nobilis cumanensis		%	52.3	48–56			49.8	34–63
Macaw, hyacinth	149	Conventional			13.4	11–16	9.2862	7.504–10.72
Anodorhynchus hyacinthinus		S.I.			13.4	11–16	9.2862	7.504–10.72
		%	50.1	45–55			69.3	56–80
Macaw, Spix's	37	Conventional			9.24 ± 2.99	2.80–15.90	5.13 ± 2.50	1.3–14.1
Cyanopsitta spixii		S.I.			9.24 ± 2.99	2.80–15.90	5.13 ± 2.50	1.3–14.1
		%	46.8 ± 3.2	36.5–53.0			56.4 ± 12.9	29.0–79.3
Macaw, yellow-collared	70	Conventional			13.6	10–16	8.6904	7.344–10.064
(Golden-collared macaw)		S.I.			13.6	10–16	8.6904	7.344–10.064
Primolius auricollis		%	50.9	42–55			63.9	54–74
Parakeet, Alexandrine	18	Conventional			14.3	10–16	8.923	7.293–10.439
Psittacula eupatria		S.I.			14.3	10–16	8.923	7.293–10.439
		%	47.4	45–54			62.4	51–73
Moustache parakeet	26	Conventional			11.6	8–15	7.6676	5.8–9.164
(Rose-breasted parakeet)		S.I.			11.6	8–15	7.6676	5.8–9.164
Psittacula alexandri		%	46.1	42–51			66.1	50–79
Parakeet, ringneck	46	Conventional			11.2	8–14	6.0144	4.48–7.616
(Rose-ringed parakeet)		S.I.			11.2	8–14	6.0144	4.48–7.616
Psittacula krameri		%	49.5	45–54			53.7	40–68
Parrot, Meyers	39	Conventional			11.2	8–14	6.9328	5.376–8.4
Poicephalus meyeri		S.I.			11.2	8–14	6.9328	5.376–8.4
		%	49.9	98			61.9	48–75
Parrot, red-bellied	14	Conventional			12.6	9–16	7.5474	7.056–8.442
Poicephalus rufiventris		S.I.			12.6	9–16	7.5474	7.056–8.442
		%	48.3	45–51			59.9	56–67

TABLE 1

Hematology: Laboratory Reference Ranges for Selected Species—cont'd

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Units	Packed Cell Volume (%) Mean	Packed Cell Volume (%) Range	White Blood Cell Count C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Mean	White Blood Cell Count C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Range	Heterophils C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Mean	Heterophils C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%) Range
Cockatoo, triton	544	Conventional			14.6	12–16	8.7892	6.424–10.95
Cacatua galerita triton		S.I.			14.6	12–16	8.7892	6.424–10.95
		%	45.5	42–50			60.2	44–75
Cockatoo, umbrella	951	Conventional			12.8	8–16	7.616	5.76–9.088
Cacatua alba		S.I.			12.8	8–16	7.616	5.76–9.088
		%	44.8	40–50			59.5	45–71
PASSERIFORMES								
Canary	300	Conventional			7	3–10	2.576	1.47–4.2
Serinus canaria forma domestica		S.I.			7	3–10	2.576	1.47–4.2
		%	49.9	45–56			36.8	21–60
Mynah species	44	Conventional			9.9	8–12	5.4945	4.455–6.336
Mostly *Acridotheres tristis*		S.I.			9.9	8–12	5.4945	4.455–6.336
		%	47.7	38–50			55.5	45–64
ANSERIFORMES								
Duck, domestic	73	Conventional			18.1	14–24	11.132	9.593–12.489
Anas platyrhynchos domestica		S.I.			18.1	14–24	11.132	9.593–12.489
		%	43.4	35–50			61.5	53–69
Swan	36	Conventional			13.4	11–16	7.1288	4.556–8.978
Cygnus sp.		S.I.			13.4	11–16	7.1288	4.556–8.978
		%	45.6	42–50	13.4		53.2	34–67
GALLIFORMES								
Chicken, domestic		Conventional				9–32		
Gallus gallus domesticus		S.I.				9–32		
		%		23–55				15–50
Quail		Conventional				12.5–24.6		
Coturnix spp.		S.I.				12.5–24.6		
		%		30–45				25–50
ACCIPITRIFORMES								
Combined eagle species	18	Conventional			16.9	12–21	11.762	8.788–13.52
Bald eagle		S.I.			16.9	12–21	11.762	8.788–13.52
Haliaeetus leucocephalus		%	41.9	37–48			69.6	52–80
Golden eagle *Aquila chrysaetos*								
Hawk, red-tailed	13	Conventional			19.5	15–24	9.7305	6.825–12.87
Buteo jamaicensis		S.I.			19.5	15–24	9.7305	6.825–12.87
		%	45.1	38–52			49.9	35–66
Common buzzard		Conventional			12.65 ± 6.90	10.17–15.12	4.63 ± 3.29	3.46–5.81
Buteo buteo		S.I.			12.65 ± 6.90	10.17–15.12	4.63 ± 3.29	3.46–5.81
		%	39 ± 5	38–41				
FALCONIFORMES								
Gyrfalcon	25	Conventional			7.3 ± 0.38	4.2–10.8	4.67 ± 0.34	2.31–8.85
Falco rusticolus		S.I.			7.3 ± 0.38	4.2–10.8	4.67 ± 0.34	2.31–8.85
		%	51.36 ± 0.90	44–59				
STRUTHIONIFORMES								
Emu	98	Conventional			14.9	8–21	11.7412	8.046–13.112
Dromaius novaehollandiae		S.I.			14.9	8–21	11.7412	8.046–13.112
		%	47.4	39–57			78.8	54–88

Lymphocytes C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%)		Monocytes C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%)		Eosinophils C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%)		Basophils C Units: $\times 10^9$/L S.I.: $\times 10^3$/μL (%)

TABLE 2
Erythrocytic Parameters[1,3]

Species Common Name (Common Name Synonyms) Scientific Name		Red Blood Cell Count (RBC) C Units: $\times 10^6/\mu L$ S.I.: $\times 10^{12}/L$		Packed Cell Volume (PCV) (%)	
		Mean	Range	Mean	Range
PSITTACIFORMES					
PSITTACIDAE					
Grey parrot	Conventional	3.27	2.84–3.62		
(African grey)	S.I.	3.27	2.84–3.62		
Genus *Psittacus* sp.	%			48.96	41.1–53.5
Amazon	Conventional	2.82	2.45–3.18		
Genus *Amazona* sp.	S.I.	2.82	2.45–3.18		
	%			47.83	41.96–52.5
Budgerigar	Conventional	4.32	3.77–4.6		
Melopsittacus undulatus	S.I.	4.32	3.77–4.6		
	%			51.45	43.4–56.1
Eclectus parrot	Conventional	2.98	2.5–3.7		
Eclectus roratus	S.I.	2.98	2.5–3.7		
	%			47.51	42.4–53.7
Lory (11 genera, 53 species)	Conventional	1.85	1.72–2.1		
	S.I.	1.85	1.72–2.1		
	%			47.4	39–57
Lovebird	Conventional	3.79	3.25–3.95		
Agapornis sp.	S.I.	3.79	3.25–3.95		
	%			48.3	41.5–55.4
Macaw group	Conventional	3.82	3.45–4.04		
Mostly *Ara* and some *Anodorhynchus*	S.I.	3.82	3.45–4.04		
	%			50.7	44.6–55.3
Parrot, Senegal	Conventional	1.8	1.70–2.17		
Poicephalus senegalus	S.I.	1.8	1.70–2.17		
	%			45	41–57
CACATUIDAE					
Cockatiel	Conventional	3.93	3.1–4.4		
Nymphicus hollandicus	S.I.	3.93	3.1–4.4		
	%			52.63	41.4–58.9
Cockatoo group	Conventional	2.84	2.44–3.34		
Family Cacatuidae	S.I.	2.84	2.44–3.34		
	%			47.1	40.2–55.12
ANSERIFORMES					
Duck, domestic	Conventional	3.61	3.2–4.01		
Anas platyrhynchos domestica	S.I.	3.61	3.2–4.01		
	%			52.06	42.3–57.7
GALLIFORMES					
Chicken, domestic	Conventional		1.3–4.5		
Gallus gallus domesticus	S.I.		1.3–4.5		
	%				23–55
Quail	Conventional		4.0–5.2		
Coturnix spp.	S.I.		4.0–5.2		
	%				30–45
STRUTHIONIFORMES					
Emu	Conventional	2.93	2.38–3.33		
Dromaius novaehollandiae	S.I.	2.93	2.38–3.33		
	%			49.38	42.2–54.6
Ostrich	Conventional	3.11	2.63–3.49		
Struthio camelus	S.I.	3.11	2.63–3.49		
	%			48.87	41.7–53.9

Hemoglobin (Hb) Conventional: g/dL S.I.: g/L		Mean Corpuscular Volume (MCV) = PCV/RBC Conventional: μm^3/cell S.I.: fl/cell		Mean Corpuscular Hemoglobin (MCH) = Hb/RBC Conventional: pg/cell S.I.: pg/cell		Mean Corpuscular Hemoglobin Concentration (MCHC) = MCH/MCV Conventional: g/dL S.I.: g/L

Enzymes: Laboratory Reference Ranges for Selected Species[1–11]

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Lactate Dehydrogenase (U/L)		Creatine Kinase (U/L)	
		Mean	Range	Mean	Range
PSITTACIFORMES					
PSITTACIDAE					
Grey parrot (African grey) Genus *Psittacus* sp.	5571	248.2	154–378	303	140–411
Grey parrot (African grey, Congo) *Psittacus erithacus*	495	243.1	144–390	306.1	135–410
Timneh parrot (African grey, timneh) *Psittacus timneh*	219	238.5	144–402	286.3	126–420
Amazon Genus *Amazona* sp.	8375	230.4	160–368	257.1	117–425
Amazon, blue-fronted *Amazona aestiva*	828	228.3	158–366	22.5	130–417
Amazon, double yellow-headed *Amazona oratrix*	565	233.3	160–354	260.9	128–420
Amazon, lilac crown *Amazona finschi*	57	225.7	160–332	248.3	153–376
Amazon, mealy *Amazona farinosa*	54	228.8	159–381	278.5	208–348
Amazon, green-cheeked (Mexican red head) *Amazona viridigenalis*	206	246.1	145–388	2435.4	123–429
Amazon, orange-winged *Amazona amazonica*	240	251.6	148–451	278.2	120–455
Amazon, panama *Amazona ochrocephala panamensis*	67	233.5	160–387	318.6	157–458
Amazon, red-lored *Amazona autumnalis*	299	229.2	150–412	262.5	136–420
Amazon, yellow-naped *Amazona auropalliata*	1074	228.5	160–360	252.5	132–402
Amazon, yellow-crowned *Amazona ochrocephala*	36	197.6	171–265	391.8	260–490
Budgerigar *Melopsittacus undulatus*	1542	251.7	156–384	235	117–368
Caique *Pionites* sp.	30	192.3	147–270	249.3	124–384
Conure group *Aratinga and Pyrrhura* sp.	2911	292.1	216–408	262.4	153–408
Conure, blue-crowned *Aratinga acuticaudata*	93	221.6	148–380	256.3	120–344
Conure, dusky (Dusky-headed parakeet, Weddell's parakeet) *Aratinga weddellii*	29	220.1	114–328	202.6	108–375
Conure, gold-capped *Aratinga auricapillus*	36	250.1	175–387	284.9	200–384
Conure, jenday *Aratinga jandaya*	55	279.7	224–354	276.8	167–388

Enzymes: Laboratory Reference Ranges for Selected Species—cont'd

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Lactate Dehydrogenase (U/L)		Creatine Kinase (U/L)	
		Mean	Range	Mean	Range
Conure, nanday *Aratinga nenday*	179	285.8	204–396	251.7	135–400
Conure, sun *Aratinga solstitialis*	57	257.7	188–392	280.1	153–372
Conure, green-cheeked *Pyrrhura molinae*	41	251.5	168–370	207.6	144–276
Conure, maroon-bellied (Red-bellied conure, brown-eared conure) *Pyrrhura frontalis*	28	281	204–372	201.5	111–491
Conure, cherry-headed (Red-masked parakeet) *Aratinga erythrogenys*	66	249.4	180–441	253.1	146–396
Conure, mitred *Psittacara mitratus*	74	212	140–360	193.2	136–311
Conure, half-moon (Orange-fronted parakeet) *Eupsittula canicularis*	29	222.2	104–368		
Conure, Patagonian *Cyanoliseus patagonus*	13			305.7	221–387
Conure, orange-fronted *Eupsittula canicularis*	13				
Eclectus parrot *Eclectus roratus*	415	275.3	198–386	264.3	132–410
Grey-cheeked parakeet (Fire-winged parakeet) *Brotogeris pyrrhoptera*	449	262.7	154–356	278.8	164–378
Lory (11 genera, 53 species)	130	194.6	124–302	295.6	178–396
Lovebird *Agapornis* sp.	650	277.1	225–354	250.7	160–392
Macaw group Mostly *Ara* and some *Anodorhynchus*	5338	135.3	70–220	214.7	88–361
Macaw, blue-and-gold (Blue-and-yellow macaw) *Ara ararauna*	1367	133.7	69–220	219.4	92–380
Macaw, green-winged (Red-and-green macaw) *Ara chloropterus*	347	139.9	72–224	220.9	96–368
Macaw, military *Ara militaris*	88	134.8	72–216	219.7	126–321
Macaw, scarlet (Red-and-yellow macaw) *Ara macao*	146	122.2	60–210	240.1	98–366
Macaw, severe (Chestnut-fronted macaw) *Ara severus*	104	128.9	66–210	225.7	123–356
Macaw, Hahn's (Red-shouldered macaw) *Diopsittaca nobilis nobilis*	51	184.8	132–260	292.8	242–380
Macaw, noble (Red-shouldered macaw) *Diopsittaca nobilis cumanensis*	22

TABLE 4

Metabolic: Laboratory Reference Ranges for Selected Species[1–11]

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Units	Uric Acid Conventional: (mg/dL) S.I.: (μmol/L) Mean	 Range	Glucose Conventional: (mg/dL) S.I.: (mmol/L) Mean	 Range
PSITTACIFORMES						
PSITTACIDAE						
Grey parrot (African grey) Genus *Psittacus* sp.	5571	Conventional S.I.	5.55 330.1	2.0–11 117.8–648.3	281.1 15.6	256–360 14.21–19.98
Grey parrot (African grey, Congo) *Psittacus erithacus*	495	Conventional S.I.	5.65 336.1	2.5–10 146.9–593.6	279.2 15.5	252–345 13.99–19.15
Timneh parrot (African grey, timneh) *Psittacus timneh*	219	Conventional S.I.	5.5 327.1	1.7–10 103.5–604.9	295.6 16.41	274–372 15.21–20.65
Amazon Genus *Amazona* sp.	8375	Conventional S.I.	5.1 303.3	2.2–10 132.0–618.0	286.6 15.91	246–378 13.66–20.98
Amazon, blue-fronted *Amazona aestiva*	828	Conventional S.I.	5.03 299.2	2.3–10 137.4–604.3	287.5 15.96	246–389 13.66–21.59
Amazon, double yellow-headed *Amazona oratrix*	565	Conventional S.I.	4.88 290.3	2.3–9.9 136.8–585.9	279.6 15.52	248–369 13.77–20.48
Amazon, lilac-crowned *Amazona finschi*	57	Conventional S.I.	5.65 336.1	2.6–10 155.2–612.6	292.1 16.21	245–353 13.60–19.60
Amazon, mealy *Amazona farinosa*	54	Conventional S.I.	5.27 313.5	2.3–12 138.6–699.5	264 14.65	201–337 11.16–18.71
Amazon, green-cheeked (Mexican red head) *Amazona viridigenalis*	206	Conventional S.I.	5.51 327.7	2.2–11 130.9–625.1	286.6 15.91	248–370 13.77–20.54
Amazon, orange-winged *Amazona amazonica*	240	Conventional S.I.	5.32 316.4	2.3–11 136.8–624.5	295.3 16.39	249–482 13.82–26.76
Amazon, panama *Amazona ochrocephala panamensis*	67	Conventional S.I.	5.58 331.9	2.8–10 164.8–606.1	272.4 15.12	248–330 13.77–18.32
Amazon, red-lored *Amazona autumnalis*	299	Conventional S.I.	5.23 311.1	2.2–9.9 130.9–587.1	285.9 15.87	250–388 13.88–21.54
Amazon, yellow-naped *Amazona auropalliata*	1074	Conventional S.I.	5.07 301.6	2.3–11 137.4–636.4	284.1 15.77	249–377 13.82–20.93
Amazon, yellow-crowned *Amazona ochrocephala*	36	Conventional S.I.	5.37 319.4	2.3–11 134.4–624.5	255.4 14.18	170–316 9.44–17.54
Budgerigar *Melopsittacus undulatus*	1542	Conventional S.I.	8.61 512.1	4.8–13 285.5–764.9	329.8 18.31	216–456 11.99–25.31
Caique *Pionites* sp.	30	Conventional S.I.	5.13 305.1	2.5–11 149.9–631.7	267.2 14.83	170–372 9.44–20.65
Conure group *Aratinga* and *Pyrrhura* sp.	2911	Conventional S.I.	6.58 391.4	3.0–11 178.4–665.0	291 16.15	216–418 11.99–23.20
Conure, blue-crowned *Aratinga acuticaudata*	93	Conventional S.I.	5.31 315.8	2.3–11 137.4–638.2	292.3 16.23	228–377 12.66–20.93
Conure, dusky (Dusky-headed parakeet, Weddell's parakeet) *Aratinga weddellii*	29	Conventional S.I.	7.52 447.3	3.1–11 186.2–644.2	273.5 15.18	213–350 11.82–19.43
Conure, gold-capped *Aratinga auricapillus*	36	Conventional S.I.	6.2 368.8	2.1–11 124.9–666.2	280.3 15.56	202–366 11.21–20.32
Conure, jenday *Aratinga jandaya*	55	Conventional S.I.	6.32 375.9	2.1–11 122.5–673.9	277.5 15.4	192–346 10.66–19.21

TABLE 4

Metabolic: Laboratory Reference Ranges for Selected Species—cont'd

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Units	Uric Acid Conventional: (mg/dL) S.I.: (μmol/L) Mean	Uric Acid Range	Glucose Conventional: (mg/dL) S.I.: (mmol/L) Mean	Glucose Range
Macaw, noble (Red-shouldered macaw) *Diopsittaca nobilis cumanensis*	22	Conventional S.I.	6.38 379.5	2.2–10 129.7–622.2	270.8 15	231–300 12.82–16.65
Macaw, hyacinth *Anodorhynchus hyacinthinus*	149	Conventional S.I.	6.79 403.9	1.5–12 91.0–734.0	271.1 15.1	216–352 11.99–19.54
Macaw, Spix's *Cyanopsitta spixii*	37	Conventional S.I.	18 ± 7.8 315 ± 132	4.6–35.8 79–602	324 ± 50.45 18.0 ± 2.8	223.42–401.8 12.4–22.3
Macaw, yellow-collared (Golden-collared macaw) *Primolius auricollis*	70	Conventional S.I.	7.44 442.5	3.4–12 204.0–702.5	278.6 15.5	126–363 6.99–20.15
Parakeet, Alexandrine *Psittacula eupatria*	18	Conventional S.I.	7.16 425.9	4.3–11 257.5–640.0	254.3 14.1	192–308 10.66–17.10
Moustache parakeet (Rose-breasted parakeet) *Psittacula alexandri*	26	Conventional S.I.	6.81 405.1	3.1–11 185.0–624.5	284.6 15.8	225–348 12.49–19.32
Parakeet, ringneck (Rose-ringed parakeet) *Psittacula krameri*	46	Conventional S.I.	6.7 398.5	3.3–12 193.9–700.7	294.4 16.34	220–354 12.21–19.65
Parrot, Meyers *Poicephalus meyeri*	39	Conventional S.I.	5.72 340.2	2.1–11 26.1–672.1	255.5 14.2	212–294 11.7–16.32
Parrot, red-bellied *Poicephalus rufiventris*	14	Conventional S.I.	6.55 389.6	3.0–9.5 178.4–562.7	275.1 15.27	232–326 12.88–18.10
Parrot, Senegal *Poicephalus senegalus*	244	Conventional S.I.	5.95 353.9	2.3–12 134.4–707.8	288.7 16.02	256–354 14.21–19.65
Parrot, thick-billed *Rhynchopsitta pachyrhyncha*	10	Conventional S.I.	6.47 384.8	3.4–11 202.2–683.4	295 16.38	246–350 13.66–19.43
Parrotlet species Genus *Forpus* sp.	29	Conventional S.I.	8.23 489.5	4.1–12 244.5–694.1	308.7 17.13	252–384 13.99–21.32
Pionus species group Genus *Pionus* sp.	431	Conventional S.I.	5.91 351.5	2.0–12 120.7–685.2	279.5 15.51	212–368 11.77–20.43
Pionus, blue-headed *Pionus menstruus*	26	Conventional S.I.	6.11 363.4	3.1–12 184.4–710.8	276.4 15.34	200–348 11.10–19.32
Pionus, white-capped *Pionus senilis*	49	Conventional S.I.	5.62 334.3	2.1–11 126.7–662.0	282.5 15.68	221–348 12.27–19.32
Quaker parrot (Monk parakeet) *Myiopsitta monachus*	210	Conventional S.I.	6.8 404.5	2.2–12 133.2–712.6	287.9 15.98	210–395 11.66–21.93
Rosella Genus *Platycercus* sp.	21	Conventional S.I.	7.22 429.4	3.4–11 201.6–634.7	337.6 18.74	281–396 15.60–21.98
CACATUIDAE						
Cockatiel *Nymphicus hollandicus*	9267	Conventional S.I.	7.05 419.3	3.4–11 202.2–648.3	326.1 18.1	228–440 12.66–24.42
Cockatoo group Family Cacatuidae	5928	Conventional S.I.	6.69 397.9	8/3/2011 226.0–654.3	267.8 14.87	206–418 11.44–23.2
Cockatoo, bare-eyed (Little corella) *Cacatua sanguinea*	30	Conventional S.I.	5.95 353.9	3.0–11 176.1–638.2	265.5 14.74	220–378 12.21–20.98
Cockatoo, Goffin's (Tanimbar corella) *Cacatua goffiniana*	298	Conventional S.I.	6.85 407.4	3.5–11 208.2–639.4	274.2 15.22	220–412 12.21–22.87

TABLE 4

Metabolic: Laboratory Reference Ranges for Selected Species—cont'd

Species Common Name (Common Name Synonyms) Scientific Name	*N*	Units	Uric Acid Conventional: (mg/dL) S.I.: (μmol/L) Mean	 Range	Glucose Conventional: (mg/dL) S.I.: (mmol/L) Mean	 Range
Cockatoo, lesser sulphur-crested *Cacatua sulphurea*	17	Conventional S.I.	6.76 402.1	2.1–11 123.7–638.2	245.2 13.61	138–304 7.66–16.88
Cockatoo, Major Mitchell (Leadbeater's cockatoo, pink cockatoo) *Lophochroa leadbeateri*	14	Conventional S.I.	7.4 440.2	2.2–11 130.9–672.1	301.9 16.76	242–392 13.43–21.76
Cockatoo, Moluccan (Salmon-crested cockatoo) *Cacatua moluccensis*	772	Conventional S.I.	6.05 359.9	3.2–11 190.3–632.9	259 14.38	198–424 10.99–23.54
Cockatoo, rose-breasted (Galah, roseate cockatoo, pink-and-grey cockatoo) *Eolophus roseicapillus*	92	Conventional S.I.	6.92 411.6	3.9–11 231.4–635.2	300 16.65	198–376 10.99–20.87
Cockatoo, triton *Cacatua galerita triton*	44	Conventional S.I.	5.55 330.1	2.2–11 127.9–654.9	270.3 15	200–345 11.10–19.15
Cockatoo, umbrella *Cacatua alba*	951	Conventional S.I.	6.67 396.7	3.5–11 208.2–648.3	269.4 14.95	214–426 11.88–23.65
PASSERIFORMES						
Canary *Serinus canaria forma domestica*	300	Conventional S.I.	8.68 516.3	4.1–13 246.2–750.0	297 16.49	160–360 8.88–19.98
Mynah species, Mostly *Acridotheres tristis*	44	Conventional S.I.	7.57 450.3	2.3–12 134.4–713.2	318.5 17.7	228–372 12.66–20.65
ANSERIFORMES						
Duck, domestic *Anas platyrhynchos domestica*	73	Conventional S.I.	6.39 380.1	2.0–12 119.0–701.3	206.5 11.46	127–319 7.05–17.71
Swan *Cygnus* sp.	36	Conventional S.I.	6.82 405.7	2.1–11 126.1–654.3	187.9 10.43	132–360 7.33–19.98
GALLIFORMES						
Chicken, domestic *Gallus gallus domesticus*	133	Conventional S.I.	4.2 249.8	0.9–8.9 53.53–529.37	206 11.35	174–239 9.6–13.17
Quail	60–150	Conventional S.I.	5.4 ± 0.23 320 ± 13.9	2.66–7 158–422	259.2 ± 10.8 14.4 ± 0.6	135–383.4 7.5–21.3
ACCIPITRIFORMES						
Combined eagle species Bald eagle *Haliaeetus leucocephalus* Golden eagle *Aquila chrysaetos*	18	Conventional S.I.	6.17 367	2.1–13 121.9–761.3	325.6 18.08	253–389 14.04–21.59
Common buzzard *Buteo buteo*	17–23	Conventional S.I.	48 ± 23.31 807 ± 392	8.8–93.74 149.0–1576.0	374.77 20.8 ± 4.6	147.75–482.88 8.2–26.8
Hawk, red-tailed *Buteo jamaicensis*	13	Conventional S.I.	11.1 658.4	6.3–18 375.9–1068.9	310.8 17.3	222–388 12.32–21.54
FALCONIFORMES						
Gyrfalcon *Falco rusticolus*	75–102	Conventional SI	2.1 ± 16.53 235.42 ± 278.66	0.9–50.2 15.32–844.31	372.43 ± 64.5 20.67 ± 3.58	271.35–580.72 15.06–32.23
STRUTHIONIFORMES						
Emu *Dromaius novaehollandiae*	98	Conventional S.I.	6.3 374.7	1.0–14 59.5–832.7	134.1 7.4	101–243 5.61–13.49

Cholesterol Conventional: (mg/dL) S.I.: (mmol/L)		Total Protein Conventional: (g/dL) S.I.: (g/L)		Albumin Conventional: (g/dL) S.I.: (g/L)		Total Calcium Conventional: (mg/dL) S.I.: (mmol/L)

TABLE 1

Classification of Selected Avian Species Groups

FALCONIFORMES	
American kestrel	*Falco sparverius*
Common kestrel	*Falco tinnunculus*
Gyrfalcon	*Falco rusticolus*
Merlin	*Falco columbarius*
Peregrine falcon	*Falco peregrinus*
Prairie falcon	*Falco mexicanus*
ACCIPITRIFORMES	
Bald eagle	*Haliaeetus leucocephalus*
Black vulture	*Coragyps atratus*
Cooper's hawk	*Accipiter cooperii*
Eurasian buzzard	*Buteo buteo*
Eurasian goshawk	*Accipiter gentilis*
Eurasian (northern) sparrowhawk	*Accipiter nisus*
Golden eagle	*Aquila chrysaetos*
Harris's hawk	*Parabuteo unicinctus*
Osprey	*Pandion haliaetus*
Red-tailed hawk	*Buteo jamaicensis*
Sharp-shinned hawk	*Accipiter striatus*
Turkey vulture	*Cathartes aura*
STRIGIFORMES	
Barn owl	*Tyto alba*
Barred owl	*Strix varia*
Eurasian eagle owl	*Bubo bubo*
Great horned owl	*Bubo virginianus*
Screech owl, eastern	*Megascops asio*
Screech owl, western	*Megascops kennicottii*
Snowy owl	*Bubo scandiacus*
RATITES	
Cassowary	*Casuarius casuarius*
Emu	*Dromaius novaehollandiae*
North Island brown kiwi	*Apteryx mantelli*
Ostrich	*Struthio camelus*
Rhea	*Rhea americana*
PICIFORMES (RAMPHASTIDAE)	
Channel-billed toucan	*Ramphastos vitellinus*
Toco toucan	*Ramphastos toco*
CICONIIFORMES	
Great blue heron	*Ardea herodias*
PHOENICOPTERIFORMES	
American (Caribbean) flamingo	*Phoenicopterus ruber*
Phoenicopterus roseus	*greater flamingo*
GRUIFORMES	
Common crane	*Grus grus*
Sandhill crane	*Grus canadensis*
Whopping crane	*Grus americana*
OTIDIFORMES	
African houbara bustard	*Chlamydotis undulata*
Chlamydotis macqueenii	*Asian houbara bustard*
CORACIIFORMES	
Rufous hornbill	*Buceros hydrocorax*

TABLE 2

Biological and Physiologic Values of Selected Psittacine Birds[1–5]

Species	Body Weight (kg)	Lifespan (Years)		Temperature °C (°F)[a]
		Range	Maximum Reported	
Amazon parrot (*Amazona* spp.)	—	>50	80	—
Amazon, blue-crowned (mealy) *(Amazona farinosa guatemalae)*	540–700	4–8	—	—
Amazon, blue-fronted *(Amazona aestiva)*	361–485 (432)	—	—	—
Amazon, double yellow-headed *(A. oratrix)*	463–694 (568)	1.5 wild	19.3 wild	—
Amazon, green-cheeked (Mexican red head) *(A. viridigenalis)*	343–377 (360)	4–8 (6)	35	—
Amazon, yellow-crowned (yellow-fronted) *(Amazona ochrocephala)*	—	—	—	—
Amazon, yellow-naped *(A. auropalliata)*	476–795 (596)	—	—	—
Amazon, white-fronted (spectacled) *(A. albifrons)*	—	—	—	—
Bourke's parakeet *(Neopsephotus bourkii)*	35–50 (40)	—	—	—
Brotogeris spp.	—	—	—	—
Budgerigar *(Melopsittacus undulatus)*	26–35	Median: 5	18	—
Cockatiel *(Nymphicus hollandicus)*	80–100	Median: 10–12	36	—
Cockatoo (*Cacatua* spp.)	—	—	—	—
Cockatoo, medium	—	—	—	—
Cockatoo, large	—	—	—	—
Cockatoo, bare-eyed (little corella) *(C. sanguinea)*	331	—	—	—
Cockatoo, citron-crested *(C. sulphurea citrinocristata)*	—	—	—	—
Cockatoo, galah (rose-breasted) *(Eolophus roseicapillus)*	299	40–60	—	—
Cockatoo, greater sulphur-crested *(C.galerita galerita)*	806	—	—	—
Cockatoo, Leadbeater's (Major Mitchell) *(Lophochroa leadbeateri)*	381–474 (423)	—	—	—
Cockatoo, lesser sulphur-crested *(C. sulphurea)*	303	—	—	—
Cockatoo, Moluccan (salmon-crested) *(C. moluccensis)*	808	—	—	—
Cockatoo, palm *(Probosciger aterrimus)*	—	—	—	—
Cockatoo, triton *(C. galerita triton)*	559	—	—	—
Cockatoo, umbrella *(C. alba)*	552	—	—	—
Conure	80–100	—	—	—
Conure, small	—	—	—	—
Conure, large	—	—	—	—
Conure, blue-crowned *(Thectocercus acuticaudatus)*	—	—	—	—
Conure, golden (Queen of Bavaria) *(Guaruba guarouba)*	252–276 (262)	—	—	—

TABLE 2

Biological and Physiologic Values of Selected Psittacine Birds—cont'd

Species	Body Weight (kg)	Lifespan (Years)		Temperature °C (°F)[a]
		Range	Maximum Reported	
Conure, nanday (black-hooded) *(Aratinga nenday)*	—	—	—	—
Conure, orange-fronted *(Eupsittula canicularis)*	—	—	—	—
Conure, Patagonian (burrowing parrot) *(Cyanoliseus patagonus)*	—	—	—	—
Conure, sun *(Aratinga solstitialis)*	120–130	Median: 19	30	—
Eclectus parrot *(Eclectus roratus)*	347–512 (432)	20–40	80	—
Grey parrot *(Psittacus erithacus)*	370–534 (407–454)	40–60 45 captivity 22.7 wild	48–60	41 (105.8)
Lory/lorikeet	—	20–30	—	—
Lorikeet, rainbow *(Trichoglossus haematodus)*	75–157	Median: 7	38	—
Lovebird	42–48	15–30	—	—
Lovebird, Fischer's *(Agapornis fischeri)*	42–58	Median: 8	32	—
Lovebird, masked (yellow-collared) *(A. personatus)*	43–47	Median: 6	24	—
Macaw	—	—	—	—
Macaw, large	—	75–100	—	—
Macaw, small	—	50–80	—	—
Macaw, blue-and-gold (blue-and-yellow) *(Ara ararauna)*	1021 995–1380 (1021)	21	48	—
Macaw, green-winged (red and green) *(A. chloropterus)*	1050–1708 (1179)	19	63	—
Macaw, hyacinth *(Anodorhynchus hyacinthinus)*	1197–1695 (1355)	22	54	—
Macaw, military *(Ara militaris)*	788–1134	Median: 20	54	—
Macaw, red-fronted *(A. rubrogenys)*	458	—	—	—
Macaw, scarlet *(A. macao)*	900–1490 (1103)	Median: 21	48	—
Pionus parrot (*Pionus* spp.)	—	—	—	—
Princess of Wales parakeet *(Polytelis alexandrae)*	100–129 (108)	—	—	—
Quaker (monk) parakeet *(Myiopsitta monachus)*	—	—	—	—
Red-crowned parakeet *(Cyanoramphus novaezelandiae)*	95–100	—	—	—
Red-rumped parakeet *(Psephotus haematonotus)*	60–69 (65)	—	—	—
Ring-necked parakeet *(Psittacula krameri)*	115	18–25	—	—
Senegal parrot *(Poicephalus senegalus)*	—	—	—	—

[a]Body temperature is not routinely measured during physical examination.
[b]Restraint can increase respiratory rate 1.5- to 2-fold.
bpm, Beats per minute; *BPM,* breaths per minute.

TABLE 3

Biological and Physiologic Values of Selected Passerine Birds[1,6–38]

Family	Species	Body Weight (g)	Lifespan (Years)		Temperature °C (°F)[a]
			Range	Maximum Reported	
Bombycillidae	Cedar waxwing *(Bombycilla cedrorum)*	30–32	—	8	40–41.3 (104–106.3)
Cardinalidae	Northern cardinal *(Cardinalis cardinalis)*	33.6–64 (42–48) Males are slightly larger than females	Annual survival rates for adults have been estimated at 60%–65%	15	40–41.3 (104–106.3)
Corvidae	—	—	—	—	40–41.3 (104–106.3)
	American crow *(Corvus brachyrhynchos)*	316–620 (438–458) Males are slightly larger	—	16 wild 59 captive	—
	Blue jay *(Cyanocitta cristata)*	64.1–109 (85)	7 wild	17 wild 26.25 captive	—
Estrildidae	—	—	—	—	40–41.3 (104–106.3)
	Bengalese finch (Society or Japanese Mövchen) *(Lonchura striata domestica)*	7.5–16	4–7	—	—
	Common waxbill *(Estrilda astrild)*	7.5–16 (8.9)	4 wild	—	—
	Gouldian finch *(Erythrura gouldiae)*	7.5–35	—	—	—
	Java sparrow *(Padda oryzivora)*	7.5–35 (24–30)	—	—	—
	Zebra finch *(Taeniopygia guttata)*	7.5–16 (12)	4–7	—	—
Fringillidae	—	—	—	—	40–41.3 (104–106.3)
	American goldfinch *(Carduelis tristis)*	8.6–20.7 (12.6)	—	10	—
	Common canary (Island or Atlantic) *(Serinus canaria)*	12–30	5–15	20–25	—
	House finch *(Carpodacus mexicanus)*	16–27 (21)	—	11	—
	Purple finch *(C. purpureus)*	18–32 (25)	2 wild	14	—
Hirundinidae	Tree swallow *(Tachycineta bicolor)*	16–25 (20)	8–11 (2.7)	12	40–41.3 (104–106.3)
Mimidae	Northern mockingbird *(Mimus polyglottos)*	36.2–58 (43–49)	—	20 captivity	40–41.3 (104–106.3)
Paridae	Black-capped chickadee *(Parus atricapillus)*	8.2–14 (10.8)	2.5 wild	12	40–41.3 (104–106.3)
Passeridae	House sparrow *(Passer domesticus)*	20.1–34.5 (27.4–28)	—	13	40–41.3 (104–106.3)
Sturnidae	—	—	—	—	40–41.3 (104–106.3)
	European starling (common) *(Sturnus vulgaris)*	64–100	—	—	—
	Golden-breasted starling *(Cosmopsarus regius)*	80	—	—	—
	Hill mynah (myna) *(Gracula religiosa)*	180–270 (205)	12	20	—
Timaliidae	Pekin robin (red-billed leiothrix) *(Leiothrix lutea)*	26	—	—	40–41.3 (104–106.3)
Turdidae	American robin *(Turdus migratorius)*	64.8–85 (77)	2 (wild) Only 25% of fledged young survive to November	14	40–41.3 (104–106.3)[c]

[a]Potential diurnal variation of 2°C to 3°C.
[b]Pip-to-hatch interval is usually 24 hours or less.[33]
[c]Less than or equal to 38°C (100.4°F) is considered slightly hypothermic in the American robin.[37]
bpm, Beats per minute; *BPM,* breaths per minute.

Heart Rate (bpm)	Respiratory Rate (BPM/min)	Clutch Size	Incubation Period (Days)[b]	Hatching Weight (g)	Eyes Open (Days)	Fledging Age (Days)	Weaning Age (Days)	Sexual Maturity (Years)

TABLE 9

Values Reported for Selected Ophthalmic Diagnostic Tests in Avian Species[1,100–116]

Species	Ultrasound (mm ± STD)[a]	Intraocular Pressure (mm Hg)		Schirmer Tear Test (mm/Minute)	Phenol Red Thread Test (mm/15 Seconds ± STD)
		Applanation Tonometry	Rebound Tonometry		
American flamingo *(Phoenicopterus ruber)*	—	16.1 ± 4.2	9.5 ± 1.7	12.3 ± 4.5	24.2 ± 4.4
Axial globe length	13.8 ± 0.16	—	—	—	—
Anterior chamber depth	1.75 ± 0.05	—	—	—	—
Lens thickness	4.6 ± 0.06	—	—	—	—
Vitreous body depth	6.95 ± 0.1	—	—	—	—
Pecten dimensions	5.1 ± 0.38 length 2.2 ± 0.14 width	—	—	—	—
Bald eagle *(Haliaeetus leucocephalus)*	—	20.6 ± 2	—	14 ± 2	—
Barn owl *(Tyto alba)*	—	—	10.8 ± 3.8	—	—
Blue-fronted Amazon[b] *(Amazona aestiva)*	—	—	—	—	—
D1	1.7 ± 0.3	—	—	—	—
D2	3.5 ± 0.2	—	—	—	—
D3	7.3 ± 0.4	—	—	—	—
Axial length	12.6 ± 0.6	—	—	—	—
Common buzzard *(Buteo buteo)*	—	17.2 ± 3.53	26.9 ± 7.0	12.47 ± 2.66	—
Chicken, 3-week-old	—	—	17.5 ± 0.1	—	—
Golden eagle *(Aquila chrysaetos)*	—	21.5 ± 3	—	—	—
Great horned owl *(Bubo virginianus)*	—	10.8 ± 3.6	—	—	—
Eurasian eagle owl *(Bubo bubo)*	—	—	10.5 ± 1.6	—	—
Eurasian sparrowhawk *(Accipiter nisus)*	—	—	15.5 ± 2.5	—	—
Japanese quail (*Coturnix coturnix japonica*)	—	—	5.8 ± 0.89	—	17.5 ± 4.17
Axial globe length	7.8 ± 0.17	—	—	—	—
Anterior chamber depth	1 ± 0.13	—	—	—	—
Lens thickness	2.4 ± 0.09	—	—	—	—
Vitreous body depth	4.4 ± 0.14	—	—	—	—
Pecten dimensions	3.5 ± 0.18	—	—	—	—
Falco sp.	—	—	—	—	30.2 ± 4.6
Kestrel *(Falco tinnunculus)*	—	8.53 ± 1.59	9.8 ± 2.5	6.2 ± 3.67	—
Humboldt penguin *(Spheniscus humboldti)*	—	—	28 ± 9	9 ± 4	—
Large psittacines[c]	—	—	—	—	19.1 ± 3.3–25.5 ± 6.3 (OS) 19.8 ± 4.3–28.2 ± 6.3 (OD)
Long-eared owl *(Asio otus)*	—	—	7.8 ± 3.2	—	—
Eurasian goshawk *(Accipiter gentilis)*	—	—	18.3 ± 3.8	—	—
Brown pelican *(Pelecanus occidentalis)*	—	—	10.86 ± 1.61	5.45 ± 1.88	—
Axial globe length	20.70 ± 0.62	—	—	—	—
Anterior chamber depth	3.38 ± 0.19	—	—	—	—
Lens thickness	5.19 ± 0.23	—	—	—	—
Vitreous body depth	12.15 ± 0.53	—	—	—	—
Peregrine falcon *(Falco peregrinus)*	—	—	12.7 ± 5.8	—	—
Pigeon	—	—	19.5 ± 4.4	—	—
Red kite *(Milvus milvus)*	—	—	13.0 ± 5.5	—	—
Red-tailed hawk *(Buteo jamaicensis)*	—	20.6 ± 3.4	—	—	—
Swainson's hawk *(Buteo swainsoni)*	—	20.8 ± 2.3	—	—	—
Tawny owl *(Strix aluco)*	—	11.21 ± 3.12	9.4 ± 4.1	3.12 ± 1.92	—
Juvenile	—	—	8.7 ± 4.9	7.2	—
Adult	—	9.4 ± 1.8	11.1 ± 3.1	4.3	—
White-tailed sea eagle *(Haliaeetus albicilla)*	—	—	26.9 ± 5.8	—	—

[a]Mean values reported.
[b]Transpalpebral ocular ultrasound examinations were performed on 32 blue-fronted Amazon parrots with no history of ocular disease; measurements were taken in sagittal planes using a 10-MHz linear probe without a standoff pad; D1 is the distance between the cornea and the anterior lens capsule; D2 is the distance between the anterior and posterior lens capsule; D3 is the distance between the posterior lens capsule and the optic papilla.
[c]Group of large parrots including 22 macaws, 17 cockatoos, 10 Amazon parrots, 1 grey parrot, 1 eclectus, and 1 pionus.
OD, Right eye; *OS*, left eye; *STD*, standard deviation.

TABLE 10

Approximate Resting Respiratory Rates of Selected Avian Species and by Weight[109–111]

Species	Respiratory Rate (BPM)[a]
Finch	90–110
Canary	60–80
Budgerigar	60–75
Lovebird	50–60
Cockatiel	40–50
Small conure	40–50
Large conure	30–45
Toucan	15–45
Amazon parrot	15–45
Cockatoo	15–40
Macaw	20–25
Mallard	30–95
Raptor	10–20
Mute swan	13–40
Weight (g)	
100	40–52
200	35–50
300	30–45
400	25–30
500	20–30
1000	15–20

[a]Restraint can increase respiratory rate by 1.5× to 2× the resting rate.
BPM, Breaths per minute

APPENDIX 4

Chick Growth Data

Brian L. Speer and Yvonne R. A. van Zeeland

A. Developmental Parameters of Selected Psittacines

Species	Day at Which Eyes First Open	Day at Which First Feathers Emerge	First Day of Perching	Last Days Unweaned
AMAZON PARROTS				
Blue-fronted *(Amazona aestiva)*	14–21	24	38–45	70–90
Blue-crowned *(Amazona farinosa)*	10–21	21	35–40	70–90
Double yellow-headed *(Amazona oratrix)*	14–21	24	38–45	70–90
Lilac-crowned *(Amazona finschi)*	10–21	21	35–40	70–90
Orange-winged *(Amazona amazonica)*	10–21	21	35–40	70–90
Red-lored *(Amazona autumnalis)*	10–21	21	35–40	70–90
White-fronted *(Amazona albifrons)*	10–21	21	35–40	70–90
Yellow-crowned *(Amazona ochrocephala)*	10–21	21	35–40	70–90
Yellow-naped *(Amazona auropalliata)*	14–21	24	38–45	70–90
COCKATOOS				
Bare-eyed *(Cacatua sanguinea)*	7–14	18–21	38–45	70–90
Citron-crested *(Cacatua sulphurea citrinocristata)*	7–14	18–21	38–45	70–90
Goffin's *(Cacatua goffini)*	7–14	18–21	38–45	70–90
Major Mitchell's *(Lophochroa leadbeateri)*	7–14	21	40–60	80–110
Moluccan *(Cacatua moluccensis)*	14–21	21	50–65	80–110
Red-vented *(Cacatua haematuropygia)*	7–14	21	38–45	70–90
Rose-breasted *(Eolophus roseicapilla)*	7–14	21	38–45	55–65
Slender-billed *(Cacatua tenuirostris)*	11–14	20	40–45	80–110
Triton *(Cacatua galerita triton)*	14–21	21	38–45	80–110
Umbrella *(Cacatua alba)*	14–21	21	50–65	80–110
MACAWS				
Blue-and-gold *(Ara ararauna)*	14–21	30–35	60–75	90–120
Buffon's *(Ara ambiguus)*	14–21	35	60–75	90–120
Green-winged *(Ara chloropterus)*	14–21	35	60–75	90–120
Hahn's *(Diopsittaca nobilis)*	14–21	35	60–75	90–120
Harlequin	14–21	35	60–75	90–120
Military *(Ara militaris)*	14–21	35	60–75	90
Red-fronted *(Ara rubrogenys)*	12–21	28–30	55–70	85–120
Scarlet *(Ara macao)*	14–21	35	60–75	90–120
Yellow-collared *(Primolius auricollis)*	10–18	21	45–55	70–90
OTHER PARROTS				
Amboina king *(Alisterus amboinensis)*	7–14	21–28	35–40	60–80
Blue-headed Pionus *(Pionus menstruus)*	10–15	20–23	40–45	
Eclectus *(Eclectus roratus)*	11–18	22–28	50–60	75–95
Grey parrot *(Psittacus erithacus)*	7–16	28	50–60	80–100
PARAKEETS				
Barraband *(Polytelis swainsonii)*	6–14	14	30–40	55–75
Barnard *(Barnardius barnardi)*	6–14	14	30–40	55–75
Princess of Wales *(Polytelis alexandrae)*	6–14	14	30–40	55–75
Rock pebbler *(Polytelis anthopeplus)*	6–14	14	30–40	55–75

B. Weight Range (in Grams) of Selected Hand-Reared Psittacine Chicks at the Avicultural Breeding and Research Center (ABRC), Loxahatchee, FL[a]

Birds were fed a home-made hand-feeding formula, made with primate diet. This diet consists of 1 quart primate diet plus 1 quart hot water that is soaked for 30 minutes prior to cooking it on the stove top to a soft boil or microwave for 8 minutes on high. Next, 2 tablespoons of smooth peanut butter, 4 ounces of dry infant oatmeal cereal, and ice cubes are added (approximately seven large cubes, to cool the mixture down, as needed). The mixture is then smoothened with a blender, hand mixer, or by hand, and water is added in case the formula is too thick. The temperature of the food is subsequently checked (should be 37.8–40.5°C/100–105°F). If needed, food can be frozen immediately after preparation, but any remaining food should always be discarded and not held for later feedings.

C. Weight[#] (Mean ± SD, Range) and Food Intake (in Milliliters) of Selected Hand-Reared Psittacine Chicks at the Aviculture Institute, Newhall, CA[a]

#Weight in grams; mean ± SD values are listed on the first line, range and number of chicks on the second line, and the third line lists the volumes administered per feed, respectively weaning age.

Birds were fed a hand-feeding formula prepared by mixing two cups of ground monkey chow (Zupreem Primate Dry Diet; Hill's Pet Products, Topeka, KA) with one cup of hand-feeding diet (Roudybush Hand Feeding Diet; Roudybush, Davis, CA) and one cup of Gerber oatmeal cereal (Florham Park, New Jersey). For chicks <3 days, this mixture is prepared with water in a ratio of 1:3, while for older chicks, the mixture is prepared with water in a ratio of 2:3.

SD, Standard deviation.

Weight ranges are derived from weight gain records of birds hand-raised from hatching to weaning. They are provided as suggested ranges only, as growth of an individual chick is dependent on hatch weight, body structure, sex, diet and feeding, and husbandry practices. Comparison of data from two successful nurseries has indicated that birds with widely divergent body weights can successfully wean.[1,2] Birds in the lower end of the weight range are more prone to stunting and should be carefully observed. Birds in the upper end of the weight range may shed excess weight at weaning. Data from this table should be combined with observation of the conformation and physical condition of the chick before deciding if an individual is stunted in growth.

E. Weight Records of Selected Species of Macaws[a]

Birds were reared using Raintree's hand-feeding formula for macaws. This home-made hand-feeding formula consists of a dry mix (one cup of ground Zupreem pellets; one cup of Gerber mixed cereal for babies; one cup of Tune-Up Mynah Pellets; three-fourths of a cup of raw peanuts, blanched without skin; one-fourth of a cup of macadamia nuts, raw and shelled; one cup raw sunflower seeds; ground fine using a meat grinder or high powered food processor and mixed) of which 1 pint is added to two and a half cups of purified water (lactated Ringer's for the first few days), 1 junior-size Gerber applesauce jar and two small jars of Gerber baby food (beechnut, banana, squash, garden vegetables, sweet potatoes, peaches, home-style creamed corn, carrots, and/or creamed spinach). This mixture is then heated to 39.7 to 41.4°C (103–106°F), stirred well for even heat, and tested with a thermometer prior to feeding.

[a]ICBP Generic rearing protocol (abbreviated):
In the first few days following hatch, chicks are reared in a still air incubator or brooder running at no lower than 35°C (95.0°F). Temperatures are reduced by 1°C per day until the secondary down feathers erupt and birds are able to thermoregulate or are returned to (foster) parents. Supplemental heating will generally no longer be required after 10 days with all but the smallest of species as long as the brooder room is set at 21°C (70°F) and not lower. Chicks are housed in containers that are designed to hold the legs neatly tucked under them to prevent splay leg. To prevent buildup of feces, containers should be washed daily. Unless dealing with chicks that weigh less than 10 g at hatch (e.g., African pygmy falcons), it is best to leave the first feed for at least 12 hours (or 24 hours for larger species), if the chick is not showing signs of hunger as overfeeding can easily occur. Chicks that look distended with fluid should be left without food until the stomach is flaccid and soft to the touch. For most species, a mixed diet of finely minced or chopped meat, consisting of skinned, gutted quail, rabbit, rats of which the head, wings/feet, tail, and gizzard (if applicable) are removed, and/or skinned mice or day-old-chicks, is suitable (Note that bones should be fed to all but the youngest of chicks as this is vital for ensuring adequate mineral intake and prevent metabolic bone disease). A good multivitamin supplement in powder form (e.g., Nutrobal, Vetark) and a probiotic supplement (e.g., Avipro Pediatric, Vetark) are added to the feed of most raptors (Note: Do not exceed recommended doses!), while in vultures, addition of digestive enzymes is common to aid in digestion. Using forceps, tiny pieces of minced food are offered to the chick, which should raise its head to accept feeding. Owls need to have the side of their beaks touched to take the food, whereas falcons may need to have food placed in the beak and their upper palate touched to stimulate them to close their beak and swallow. New-world vultures, in contrast, naturally feed by putting their beaks inside the parents' beak to receive regurgitated food, which can be mimicked by gently encircling the beak with finger and thumb (behind which food is presented with a forceps). All other diurnal raptors will generally attempt snatching food from a forceps that is slowly brought toward the beak at about eye level. Damping the food is recommended to facilitate feeding and prevent dehydration (Note that young raptors do not drink until they have left the nest and can reach water for themselves but do obtain additional fluids with their feed from the oral secretions that are dripped onto the food by their parents). Four feeds per day are generally sufficient to stimulate adequate growth, with the exception of the smallest chicks (<10 g). Weighing before and after every feeding is recommended to adequately evaluate food intake and growth. Casting materials to allow the young bird to form pellets for regurgitation can be introduced in the food by stopping skinning of day-old chicks at about 10 to 14 days of age for small to medium-sized birds and up to 1 month for larger birds. An exception to this rule is the small birds such as merlins, which do better without casting material until they are feathering up. Ringing of the young is recommended at 10 to 14 days of age for most species. Whenever possible, chicks should be returned to their (foster) parents at 10 to 12 days of each, provided that they are looking healthy, eating well, and have been ringed; if this is not possible, contact and handling by the human caretakers should be minimized and involve the use of puppets shaped to the color and build of the adult to prevent severe imprinting. Whenever returning a young bird to its (foster) parents, it is necessary to intensely monitor them for at least several hours, up to 1 or 2 days, to ensure that everything is going well, and continue the monitoring throughout the rearing period to ensure that everything is going well.
Full version of the ICBP protocol is available at: https://www.handrearingresourcecenter.com/.
Data as shown were generously provided by Jemima Parry-Jones at the International Centre for Birds of Prey (ICBP), Newent, Gloucestershire, UK, and analyzed by Katie Wellfair.

G. Feeding Schedule and Expected Weight Gain in Selected Columbiformes

G.1. Feeding Schedule for Rock Pigeons *(Columba livia)*

Home-made diet for squabs: mix one hard-boiled egg yolk (mashed) with 3 tablespoons of mixed baby cereal, 3 tablespoons of oatmeal, and 3 tablespoons of cornmeal.[a] Alternatively, a mixture of Emeraid (Lafeber Company, Cornell, IL) mixed with a psittacine neonatal formula (e.g., Kaytee Exact, Chilton, WI) can be used in a ratio of 1:1. Consistency of the food should gradually be increased[b]:

- Hatch to Day 2: 1 part formula to 6 parts water
- Days 2 to 5: 1 part formula to 2 or 3 parts water
- Day 5 to weaning: 1 part formula to $1^1/_3$ to 2 parts water.

Check crop and feed when nearly empty. Food expires after 1 hour: discard and mix fresh at each feeding. NOTE: DO NOT FEED COLD FOOD!

[c]Normally there is no need to feed chicks at night.
[d]Often, tube-feeding is no longer necessary at this weight.
Adapted from: Eilertsen N, Purdin G: Pigeons and doves. In: Duerr RS, Gage LJ, editors: *Hand-rearing birds*, ed 2, 2020, Wiley Blackwell, Hoboken, New Jersey, pp 437–456.

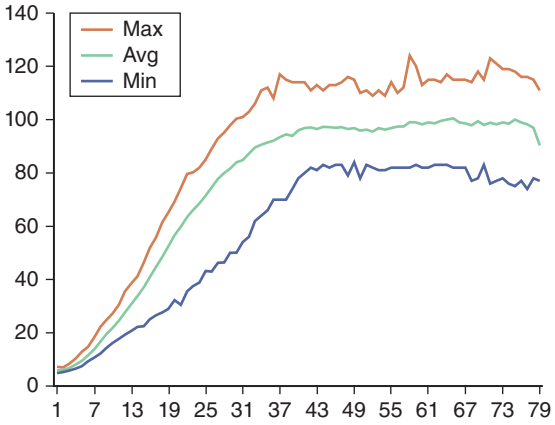
G.4. Growth Curves for Rock Pigeons and Mourning Doves



Note: Pigeon and dove chicks typically reach adult weight by 3 to 4 weeks of age. Chicks should gain weight daily until they have finished growing. Chicks should be weighed before the first feed of the day to avoid confounding from the amount of food in the crop. Images reprinted from: Eilertsen N, Purdin G. (2020). Chapter 27: Pigeons and doves. In: Duerr RS, Gage LJ, editors: *Hand-rearing birds*, ed 2, Hoboken, 2020, Wiley Blackwell Publishing, pp 437–456.

Emerald toucanet (*Aulacorhynchus prasinus*)

Hand-feeding is performed using Mazuri commercial hand-feeding formula (Mazuri Exotic Animal Nutrition, PO Box 66812, St. Louis, MO 63166) mixed with distilled water to a consistency of pea soup. To this, pureed commercial canned fruit for babies is added at a ratio of 5% to 10% fruit to formula. For the first few days, initial feedings comprise no more than 5% of the bird's body weight (total amount). The amount fed is gradually increased based on the bird's increasing body weight such that by 6 weeks of age, the bird is receiving 9% to 10% of its body weight for total daily feeding. During the first 3 weeks of life, birds are fed nine times per day at 2-hour intervals. As feeding of toucan chicks requires more time (30 vs 5 minutes in a psittacine chick), this leaves a gap of 6.5 hours during the night. Reprinted from St. Leger J, Vince M, Jennings J, McKerney E, Nilson E, et al: Toucan hand-feeding and nestling growth, *Vet Clin North Am Exot Anim Pract* 15(2):183–193, 2012, with permission.

metabolic laboratory reference ranges for, e69–e76t
palatine luxation in, 472f
postoperative tracheostomy in, 417f
rhamphothecal overgrowth, 459f
sinus trephination in, 411f
sinusotomy in, 411f
tactile pits in, 450f
weight records of, e116–e118t
Ara chloropterus (macaw, green-winged)
chemotherapy prophylaxis for, 173t
chick
food intake, e110t
weight gain of, e114t
weight range of, e107t
enzymatic laboratory reference ranges for, e58t
feather loss on, 520f
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
palatine luxation in, 472f
rhamphothecal overgrowth in, 460–461f
weight records of, e120–e122t
Ara glaucogularis (macaw, blue-throated)
chick
weight gain of, e114t
weight range of, e107t
weight records of, e131–e133t
Ara macao (macaw, scarlet)
chick
food intake, e110t
weight gain of, e114t
weight range of, e107t
enzymatic laboratory reference ranges for, e58t

Ara macao (macaw, scarlet) *(Continued)*
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
ramp orthosis in, 463f
sinusotomy in, 410f
weight records of, e129–e131t
Ara militaris (macaw, military)
chick
food intake, e110t
weight gain of, e114t
weight range of, e107t
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
weight records of, e125–e127t
Ara rubrogenys (macaw, red-fronted)
chick
food intake, e110t
weight gain of, e114t
weight range of, e107t
weight records of, e127–e129t
Ara severus (macaw, severe)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga acuticaudata (conure, blue-crowned)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga auricapillus (conure, gold-caped)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga jandaya (conure, Jenday)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga nenday (conure, nanday)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga solstitialis (conure, sun)
enzymatic laboratory reference ranges for, e58t
feather cyst in, 507f
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Aratinga spp.
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
Aratinga weddellii (conure, dusky)
enzymatic laboratory reference ranges for, e58t
hematologic laboratory reference ranges for, e45t
metabolic laboratory reference ranges for, e69–e76t
Ardeotis kori (kori bustard), chemotherapy prophylaxis for, 173t
Area under the curve (AUC) concentration, 84
Arginine vasopressin, e21–e22t
Arginine vasotocin, e21–e22t
Arildone, 224
Aristotle, 855
Armor All Protectant, e33t
Arsenic, 823–824
Artemisinin, 204t, 207–208
Artifacts
computed tomography, 45f, 45–47, 46f, 47f, 48f

  treatment of, decision-making process for, 611
  triage and treatment of, 617–620, 619f, 619f
  triage for, 572
Franklin's gulls. *See Leucophaeus pipixcan*
Free flight, 775f, 775–776
Free lofting, falconry, 844–845t
Free-ranging birds of prey, *Chlamydia buteonis* in, 304–305, 305f, 306t
Freezing injuries, triage for, 575
Fregatidae, biological and physiologic values of, e95–e97t
Fringilla coelebs (common chaffinch), antimicrobial resistance in, 106–131t
Fringillidae
  antimicrobial resistance in, 106–131t
  biological and physiologic values of, e85t
Frizzled feathers, 498, 499f
Frostbite, triage for, 575
Fulica atra (Eurasian coot)
  antimicrobial resistance in, 106–131t
Full-thickness burns, 830
Fumagillin, 183–186t
Fungal culture, for cryptococcosis, 328–329
Fungal infections
  in chick, 690
  in feathers, 513–514, 514f
  lung/air sac, 400f, 400–401
  lungs and/or air sacs disease *vs.*, 384–386t
  nasal/sinus disease *vs.*, 382–383t
  ocular, 182
  in toucan chicks, 725
  tracheal disease *vs.*, 383–384t
Fungi, 217–218
Furaltadone, for spironucleosis, 349t, 351
Furosemide, e32t

G

Gabapentin, 587–588, 588t, e15–e18t, e26–e27t
Gadolinium-based contrast medium, 48–49
Gadopentetate dimeglumine, e36t
Galah. *See Eolophus roseicapilla*
Galliformes
  antimicrobial resistance in, 106–131t
  biological and physiologic values of, e89–e88t
  circovirus in, 511–512t
  pododermatitis in, 553–555
    clinical and pathological findings of, 546t, 554–555, 555b, 554f
    pathophysiology of, 554
    treatment and prevention of, 555
  pterylosis in, 488b
Gallus gallus domesticus (chicken, domestic)
  antimicrobial resistance in, 106–131t
  pododermatitis in, 554f
  ringworm in, 514f
Game launchers, for falconry training, 848–849, 849f
Ganglioneuritis, avian, 689
Gape, 442t
Garlic powder, for egg composition, 638b
Gas exchange, in birds, 371, 373f
Gastrointestinal and hepatic agents, e34t
Gastrointestinal disorders
  in chick, 693–695
  in raptor chicks, 710f, 710, 712f
Gastrointestinal effects, of petroleum products, 814
Gastrointestinal foreign body, in chick, 694–695, 695f
Gastrointestinal tract system, development of, in precocial birds, 729
Gastrointestinal yeast infection, 178–179
Gauntlet, falconry, 844–845t
Gavia pacifica (Pacific loon), antimicrobial resistance in, 106–131t
Gaviiformes, antimicrobial resistance in, 106–131t
Genetically acquired color mutations, in feathers, 515
Gentamicin, e1t–e6t, e23t
Gentamycin sulfate, e30t
Gentoo penguins. *See Pygoscelis papua*
Geopelia cuneata
  enzymatic laboratory reference ranges for, e58t
  hematologic laboratory reference ranges for, e45t
  metabolic laboratory reference ranges for, e69–e76t
Germ, establishment of, 638

Respiration rate, 379

Respiratory arrest, basic life support in, 566f, 566
Respiratory aspergillosis, 400
Respiratory cycle, 374, 375f, 376b
Respiratory distress
  anatomical location involved in, 381b
  assessment for, 828
  flow diagram of, 390b
  triage for, 569–570, 570f
Respiratory pharmacology, 405
Respiratory sounds, 378
Respiratory system, 361
  diagnostic workup of, 378–394, 381b, 382–383t, 383–384t, 384–386t, 386t
    biochemistry, 391–393
    blood gas analysis, 392t, 393, 393t
    conventional radiography *versus* computed tomography, 393f, 393–394
    hands-on physical examination, 379–380
    hematology, 391–393
    nasal and sinus flushing, 387, 391f
    observational assessment from a distance, 379
    patient history, 378–379
    sinus aspirate, 391, 391f
    swab collection from choanal slit, 387–391
    tracheal swabs or lavage, 391
  endoscopy, 422
    cameras, 422, 424f
    diagnostic procedures, 428–433
    endoscopy equipment, 422–428, 423–424t
    equipment, 422–428, 423–424t
    flexible instruments, 425, 426f
    light sources, 422
    mobile units, 424, 425f
    multiple-entry endosurgery, 426f, 426–428
    photodocumentation, 422–424
    telescopes and sheaths, 425f, 425
    therapeutic, endosurgery and, 433–438, 436f
  extrapulmonary factors of, 376f, 376
  lower, 368–376
    defense mechanisms of, 375–376
    large airways, 368, 370f
    lung-pulmonary air sacs, 365f, 368–374, 371f, 372f, 373f, 374f
  respiratory cycle in, 374, 375f, 376b
  upper, 361–368
    larynx, 366f, 366–368
    nasal and sinusal cavities, 361–366, 362f, 363f, 364–365f, 365f
    syrinx, 366–368, 367f, 369f, 370f
    trachea, 366–368, 367f
Respiratory tract
  auscultation, in chick, 681–682
  diseases of, 395–405
    air sac compression, 403
    airflow occlusion, 403
    lung/air sac, 399–403
    nasal and sinus, 395–397, 396f, 397f, 398f
    therapeutic principles for, 403–405
    trachea, 398f, 398–399, 399f
  surgery of, 407
    lower, 420–421
    patient preparation, 407
    principles, instrumentation, and material, 407
    upper, 407–420
Responsible Use of Medicines in Agriculture Alliance (RUMA), 134t
Resting respiratory rates, of avian species, by weight, e99t
Restraint, low-stress, 746–754, 745.e1–745.e3b, 747t
  tools for, 747, 748f
Resuscitation, fluid for, 568–569, 569b
Reticulate scales, of avian feet, 531–532, 532f
Retirement, 23, 25–26
Retraction, of maxillary beak, 442t
Rhamphotheca, 442t
Rhinitis, 395, 144t, 146t, 154t, 158t
Rhinolithiasis, nasal/sinus disease *vs.*, 382–383t
Rhinoliths, 396f
  removal, 407–409, 408f
Rhinoscopy, 429, 430f
Rhinotheca, 442t
Rhinotomy, 407–409, 408f
Rhynchokinesis, 442t
Rhynchopsitta pachyrhyncha (parrot, thick-billed)
  chicks, weight range of, e107t
  enzymatic laboratory reference ranges for, e58t
  hematologic laboratory reference ranges for, e45t
  metabolic laboratory reference ranges for, e69–e76t
Ribavirin, 222–223, 223f
Rickettsia, in cats, 837
Rictus, 442t
Rifabutin, e1t–e6t
Rifampin, e1t–e6t, 225
Rifamycins, 225
Rigid instruments, 426, 428f, 429f
Rima glottidis, 366
Rimantadine, e10t
Rimantadine hydrochloride, 223–224
Ring artifact, 46–47
Ring-billed gull. *See Larus delawarensis*
Ringneck parakeet. *see Psittacula krameri*
Ripuarian Law, 855
Roadside hawk. *See Rupornis magnirostris*
Robenacoxib, 584t, 585–586, e19–e20t
Robotic prey, for falconry training, 862f, 863f, 862–863
Rock pigeons. *See Columba livia domestica*
Rocuronium bromide, e30t
Rodenticides, 821–822, 821t, 822f
Ronidazole, e11–e14t
  for giardiasis, 348, 349t
  for trichomoniasis, 340, 341t
Rooks. *See Corvus frugilegus*
Roost mites, 514
Rose-breasted cockatoo. *See Eolophus roseicapilla*
Rostrum, 442t
Rosuvastatin, e32t
Rosy starling. *See Pastor roseus*
Rotary hand tool, 7
Roundworms, in cats, 837–838
Rupornis magnirostris (roadside hawk), antimicrobial resistance in, 106–131t
Russell Luff Meredith, 864

S

Saffron toucanet. *See Baillonius bailloni*
Sagittariidae, characteristics of, 544b
Saker falcon. *See Falco cherrug*
Salbutamol, e32t
Salic Law, 855
Salmonella typhimurium, 251
Salmonellosis, 67
Salpingitis, 144t, 158t
Salt gland, 362
Santa Cruz ground doves. *See Pampusana sanctaecrucis*
Sarcocystis falcatula, 401–402
Sarcocystosis, 202b, 202–203
Sarcogyps calvus (red-headed vultures), antimicrobial resistance in, 106–131t
Scaly face mite, 514
Scaly-headed parrot. *see Pionus maximiliani*
Scarlet macaw. *See Ara macao*
Scissors, 7
Scissors beak. *See* Lateral beak deviation
Sclater's crowned pigeons. *See Goura sclaterii*
Screech owl. *See Megascops* spp.
Screen-film radiography, 30
Scutella scales, of avian feet, 531
Scutellate scales, of avian feet, 531
Scutes, of avian feet, 531
Sea salt and lysozyme spray/foam, for wound, 598t, 601
Searching, in birds, 789t
"Second-degree" burns, 830
Secondary dressings, for burn wounds, 832
Sedation, 567–568
Selamectin, e11–e14t
Selection, in birds, 789t
Selenidera piperivora (Guyana toucanet), growth curves for, e141f
Selenium, e28–e29t
  for egg composition, 638b
Self-maintenance behaviors, 789–790
Semiocclusive polyurethane membrane coated with acrylic adhesive, 602t, 603
Semiplumes, 482, 486f
Senegal parrot. *See Poicephalus senegalus*
Sensitization, 738t
Sensory effects, of petroleum products, 814
Sensory enrichment, 782–785
Septic arthritis, 144t, 146t, 152t, 154t, 158t
Septicemia, 144t, 146t, 152t, 154t, 158t
Serinus canaria (Norwich canary), feather cysts on, 498f
Serinus canaria forma domestica (canary)
  enzymatic laboratory reference ranges for, e58t
  hematologic laboratory reference ranges for, e45t
  metabolic laboratory reference ranges for, e69–e76t
Serrated bill tomia, in toucans, 878
Severe macaw. *See Ara severus*
Shape, term, 75
Shaping, in positive reinforcement training, 773b
Shark liver oil, for pododermatitis, 537t
Sharp-shinned hawk, 871
Sheaths, 425f, 425
Shell, in egg formation, 640f
Shell gland, in egg formation, 635b, 636
Shock, assessment for, 828
Shoulder girdle
  fracture management of, 620, 621f, 622f
  luxation of, management of, 629
Shoveler duck. *See Anas clypeata*
Show clip, 757f
Sildenafil, e32t
Silkiness, 498, 499f
Silver, for pododermatitis, 537t
Silver gull. *See Chroicocephalus novaehollandiae*

Silver sulfadiazine, e1t–e6t, 183–186t, 598t, 601, 831–832,
Silymarin, e34t
Single-use mop, 240
Sinus, diseases, 395–397, 396f, 397f, 398f
Sinus aspirate, 391, 391f
Sinus flushing, 387
Sinus trephination, 411f, 411–412, 412f
Sinuscopy, 429, 430f
Sinusitis, 144t, 146t, 154t, 158t, 395, 687t,
Sinusography, 35
Sinusotomy, 396f, 396, 410f, 410–411, 411f
Size, term, 75
Skin
  avian, 590
  tilapia, for wound, 602t, 603
Skin flaps, for wound, 595–596f, 595–597, 597f
Skin grafts, for wound, 595–596f, 595–597, 597f
Skin trauma, 144t
Skin-So-Soft, e33t
Skull fracture
  growing, in raptor chicks, 715
  management of, 628
SLD. *See* Spotty liver disease
Slip, falconry, 844–845t
Small anesthetic face masks, 8
Small animals, welfare of, impact of feral cats on, 836f, 836
Small-tipped culture swabs, 8
Smoke inhalation, 828
Snowy egret. *See Egretta thula*
Snowy owls. *See Bubo scandiacus*
Social enrichment, 764–772, 770f, 771f
Social imprinting, in precocial birds, 731f
Social media, 20
Sodium bicarbonate, e31t
Sodium chloride, e23t
Sodium fusidate, for pododermatitis, 537t
Sodium hypochlorite (household bleach), 244
Soft laser, 183–186t
Soft ringed capture net, 7, 8f
Soft tissue injuries, triage for, 573–576
Soft tissue sarcoma, 403f
Sour crop, 693–694, 694f
South America, falconry in
  in future, 877
  in past, 876–877
  in present, 877
Soy oil supplementation, for egg composition, 638b
Spar, 858
Special senses, development of, in precocial birds, 729
Specialized nonadherent gauze pads, 602t, 603
Specialty board certification, avian veterinarian and, 3
Species composition, 234–235
Species-specific response, to analgesics, 829
Spectinomycin, e23t
Sperm selection, storage, and transport, 636–638, 637f, 638b
Sphenisciformes
  antimicrobial resistance in, 106–131t
  circovirus in, 511–512t
  pododermatitis in, 557–558
    clinical and pathological findings of, 558f, 557–558, 558t
    pathophysiology of, 557
    treatment and prevention of, 559f, 558
  pterylosis in, 488b
Spheniscus demersus (African penguin)
  chemotherapy prophylaxis for, 173t
  pododermatitis in, 559f
SPIDER (Setting goals, Planning, Implementing, Documenting, Evaluating, and Readjustment) model, 790, 791b
Spilopelia senegalensis (laughing dove)
  antimicrobial resistance in, 106–131t
Spinal trauma, triage for, 571f, 571–572, 572f, 573f, 574f
Spine, fracture management of, 628
Spinosyn, 210t
Spinosyns, 213
Spinus tristis (goldfinch), antimicrobial resistance in, 106–131t
Spiraled feathers, 498, 500f
Spironolactone, e32t
Spironucleosis, 350, 351f
  diagnosis of, 350
  treatment, prevention, and control of, 349t, 351
Spironucleus, 348–351
Spironucleus columbae, 350
Spironucleus meleagridis, 348–350, 350f
Splay legs
  in chick, 687t, 697f, 697–698, 698f
  in raptor chicks, 711t
Splints, for phalangeal fractures, 627, 628f, 629f, 630f
Split-product vaccine, 248
Spotless starling. *See Sturnus unicolor*
Spotty liver disease (SLD), 293
Squamous cell carcinoma
  in beaks, 452f, 452
  in glottis, 397, 398f
STA solution, 183–186t
Stabilization, triage and, 563–576
Stainless steel orthopedic wire, for beak repair, 462t
Staphylococcus spp., in chick, 690
Stationing, 746f
Steatitis, 75f
Steppe eagle. *See Aquila nipalensis*
Stereotypic behavior, enrichment for, 793b
Sterile water, e23t
Sterilized cotton-tipped applicators, 9
Sternostoma tracheacolum, 214, 402,
Steroids, e21–e22t
Stethoscopes, disinfected, 240
Stifle, luxation of, management of, 630
Stimulus fading, 738t
Stomatitis, 146t, 152t, 154t
Stone curlew, 851–852
Stratum basale, of avian feet, 530
Stratum corneum, of avian feet, 530
Stratum germinativum
  of avian feet, 530
  of skin, 590
Stratum intermedium, of avian feet, 530
Stratum transitivum, of avian feet, 530
Straw feathers, 496
Streptomycin, e1t–e6t
Streptopelia decaocto (Eurasian collared doves), feeding schedule for, e137t
Streptopelia risoria
  enzymatic laboratory reference ranges for, e58t
  hematologic laboratory reference ranges for, e45t
  metabolic laboratory reference ranges for, e69–e76t
Streptopelia turtur (European turtle dove), antimicrobial resistance in, 106–131t
Stress
  diagnostic sample collection, 755
  hospitalization, 755–756, 756f
  during physical examination, 733
  physiological and behavioral impact of, 733–734
  response, 733
  treatment plan development, 755
Stress lines, in feathers, 502–503, 503f
Stress response
  defined, 733
  of petroleum products, 816
Stressor, 734
Strictures, 433–434, 436f, 437f
Stridor
  differential diagnosis for, 383–384t
  nasal, 378
Strigiformes
  antimicrobial resistance in, 106–131t
  antimicrobial use in, 152t
  avian species groups, e79t
  biological and physiologic values of, e86t
  circovirus in, 511–512t
Strigops habroptilus (kakapo), erysipelas in, 312t
Strix varia (barred owl), antimicrobial resistance in, 106–131t
Structural colors
  of barbs, 495
  of barbules, 495
  of feathers, 492–495
Struthio camelus (ostrich)
  enzymatic laboratory reference ranges for, e58t
  erythrocytic parameters for, e57t
  hematologic laboratory reference ranges for, e45t
  metabolic laboratory reference ranges for, e69–e76t
Struthioniformes
  circovirus in, 511–512t
  pterylosis in, 488b
Strychnine, in rodenticides, 821t, 822
"Stuck in molt," 507
Stunting, in chick, 687t, 695–697, 696b, 696f
Sturnidae
  antimicrobial resistance in, 106–131t
  biological and physiologic values of, e85t
Sturnus unicolor (spotless starling)
  antimicrobial resistance in, 106–131t
Subaortic ventricular septal defect, 74f
Subocular sac, 362–363
Subunit vaccine, 248
Subunit vaccines, 247t
Sucralfate, e34t
Sujan Singh, 853
Sulfachloropyrazine, e11–e14t
Sulfachloropyridazine, e11–e14t
Sulfadimethoxine, e1t–e6t, e11–e14t, e23t
Sulfaquinoxaline, e11–e14t
Sulfonamides, 194–198t, 204t, 209t
Sulfur, 217
Sulidae, biological and physiologic values of, e95–e97t
Suliformes
  antimicrobial resistance in, 106–131t
  circovirus in, 511–512t
Sulphur-crested cockatoo. *See Cacatua galerita*
Sun conure. *See Aratinga solstitialis*
Sunbathing, 879, 882
Supplemental therapy, 182

Surgery, for pododermatitis, 538–539, 539–540f, 540–541b, 541–542f
Surgical fracture management, 614–617, 617f, 618f, 619f
Surgical hemostatic clips, 9
Surgical instruments, 9
Surgical laser, 9
Surgical site infection, development of, 169–170
Susceptibility artifact, 49–50
Susceptibility testing, 92–93, 92t, 93f
Swabs, collection of, from choanal slit, 387–391
Swainson's toucan. *See Ramphastos swainsonii*
Swan. *See Cygnus* sp.
Swimming feet, 533
Swivel, falconry, 844–845t
Symmetry, in chick, 679
Syndactyl feet, 533
Syngamus, 192–193, 192t, 193b
Syngamus spp., 192, 192t, 193b
Synthetic prosthesis, 442t, 474, 475f, 476f
